Lund, March 2014

THE PROPAGATION

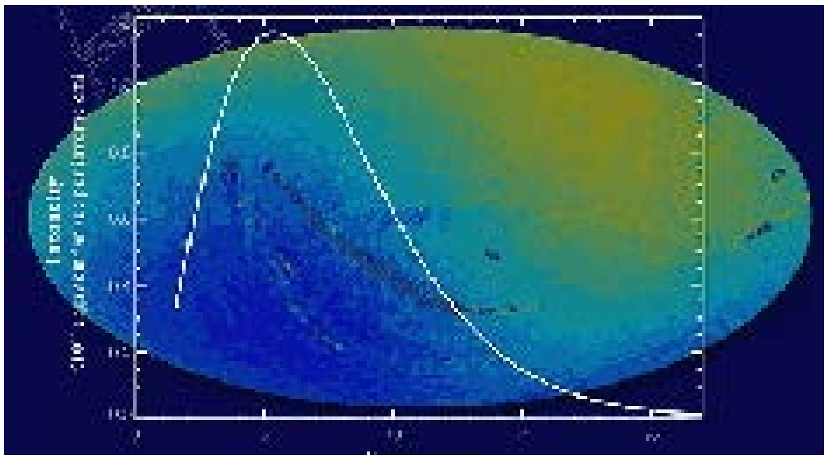
INTERACTION WITH THE SOLAR SYSTEM AND THE EARTH

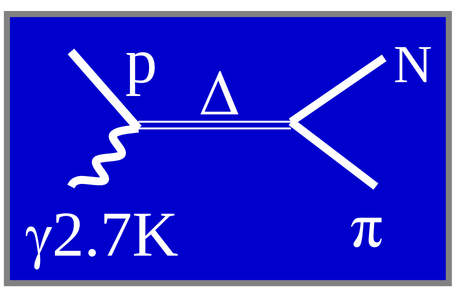
Propagation of charged CR in the Universe

- Gyroradius
- B in the Galaxy: a few μG; outside the Galaxy: 1nG > B > 1 pG
- If you want to look at the GC (d ~ 8 kpc) you need E > $2\ 10^{19}$ eV
  - But only 1 particle / km2 / year
  - And: no galactic emitters expected at this energy
- But in principle one could look outside the galaxy, were B is smaller and there are SMBHs…
  - No: the GZK cutoff provides a maximum E ~ 10^{19} eV

$$\frac{r}{1\ \text{pc}} \cong \frac{\frac{E}{1\ \text{PeV}}}{\frac{B}{1\ \mu\text{G}}}$$

The Greisen-Zatsepin-Kuzmin (GZK) cutoff

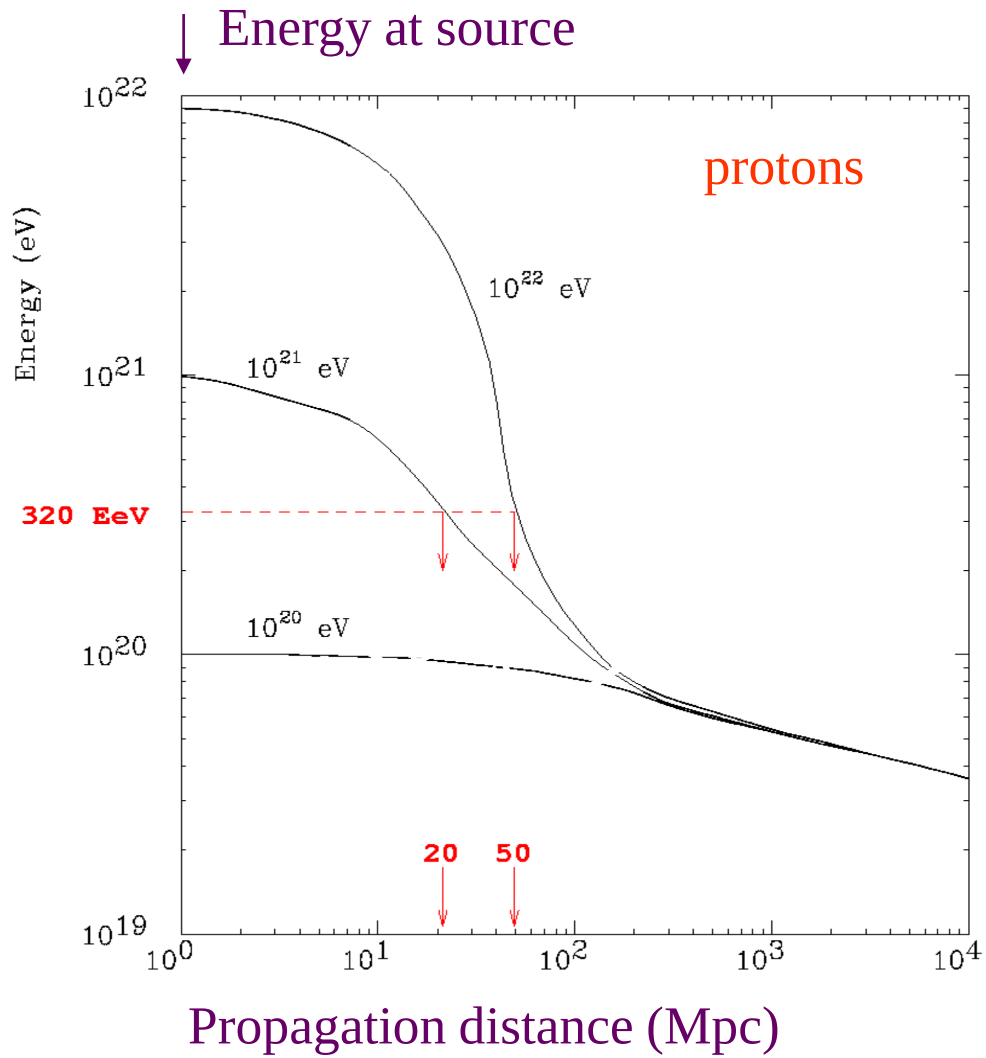




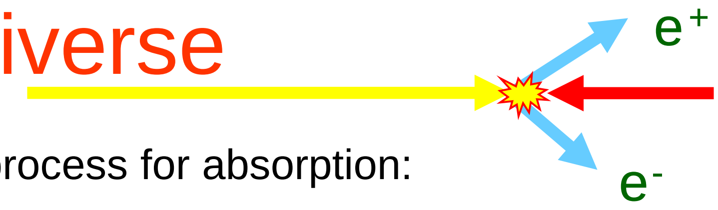
$E_p \approx 10^{20}\,\mathrm{eV}$

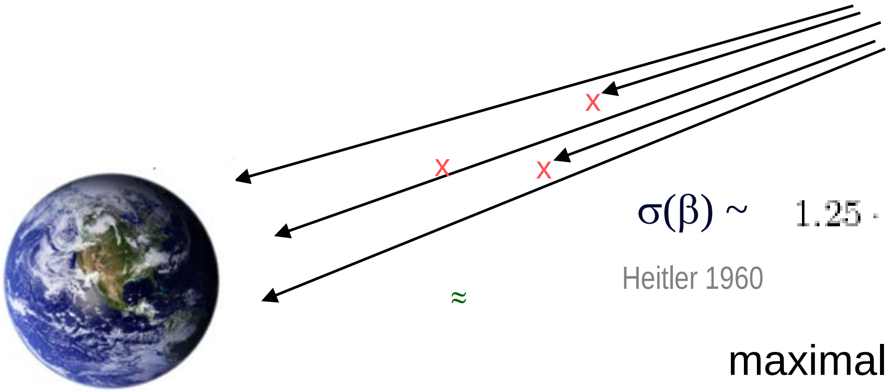
$$\lambda = \frac{1}{\sigma_{p\gamma}\,\rho_{CMB}}$$

$$\approx 6\ \mathrm{Mpc}$$



Propagation of γ-rays in the Universe





dominant process for absorption:

$$\gamma_{VHE}\gamma_{bck} \rightarrow e^+e^-$$

$$\sigma(\beta) \sim 1.25 \cdot 10^{-25}(1-\beta^2)\cdot\left[2\beta(\beta^2-2)+(3-\beta^4)\ln\left(\frac{1+\beta}{1-\beta}\right)\right]\,\mathrm{cm}^2$$

Heitler 1960

maximal for: $\boxed{\epsilon \simeq \frac{2m_e^2c^4}{E} \simeq \left(\frac{500\ \mathrm{GeV}}{E}\right)\mathrm{eV}}$

- For gamma rays, relevant background component is optical/infrared (EBL)
- different models for EBL: minimum density given by cosmology/star formation

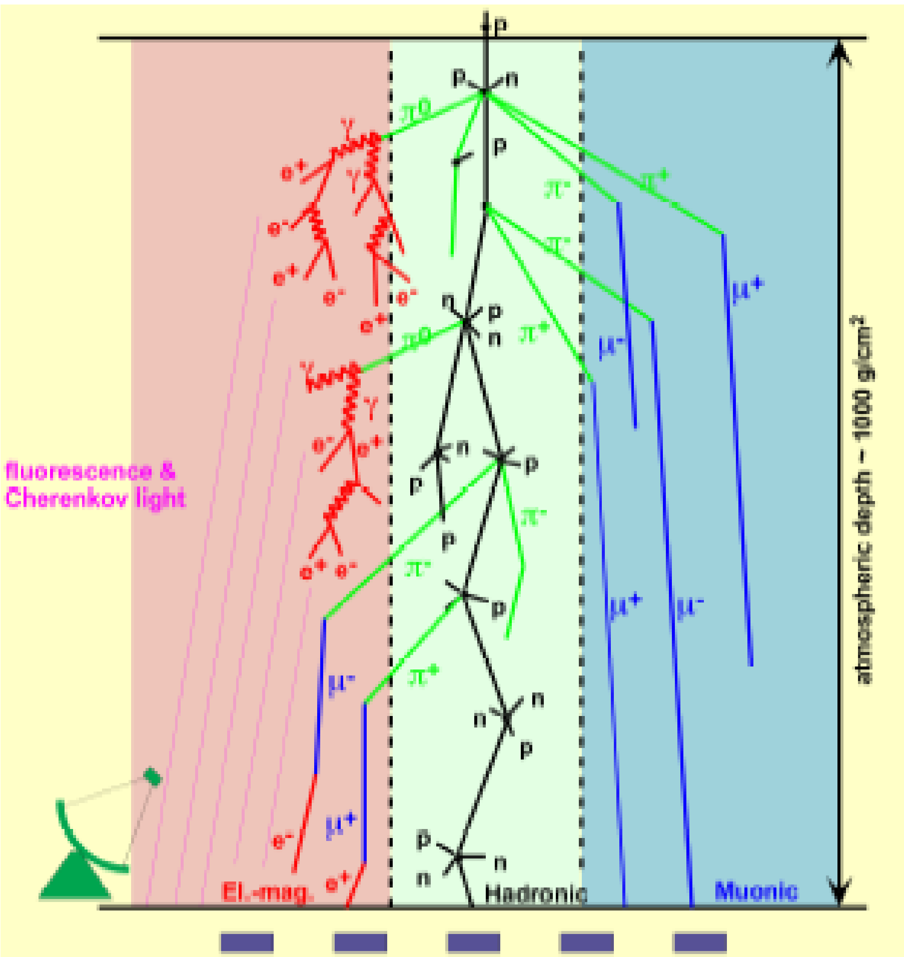
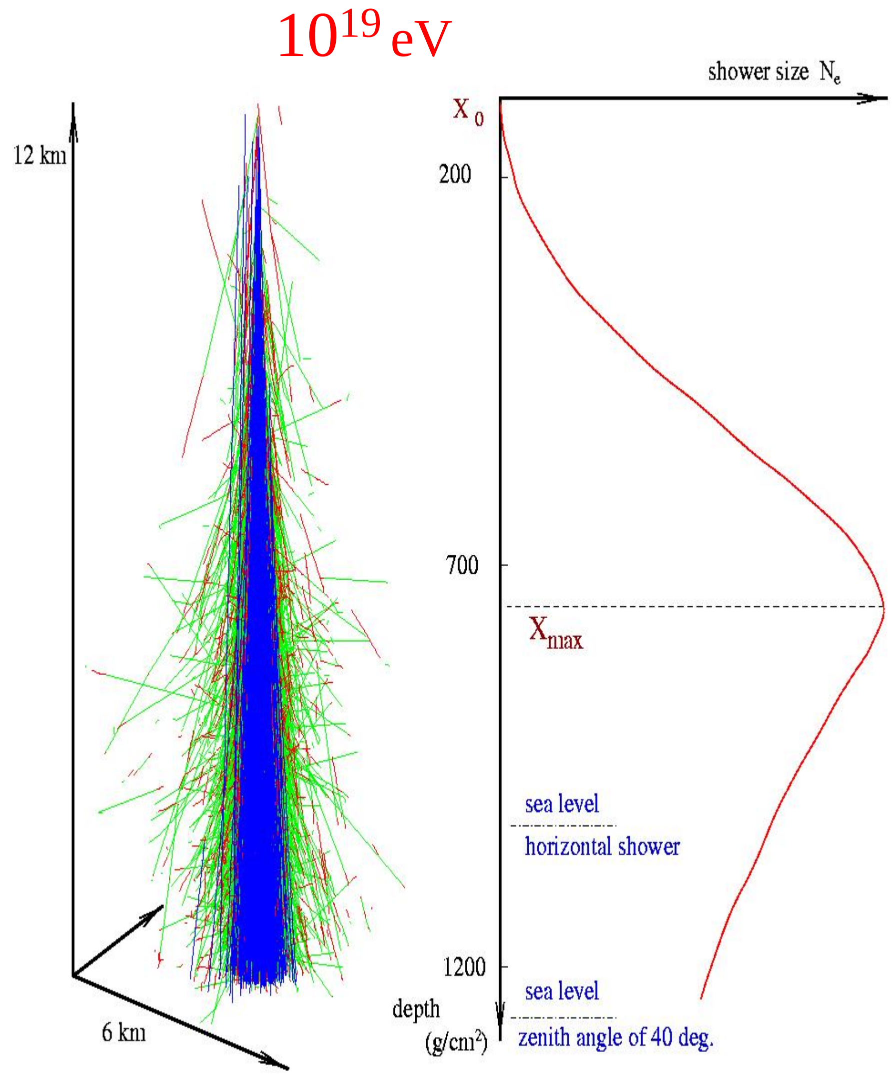
Extensive Air Showers (EAS)

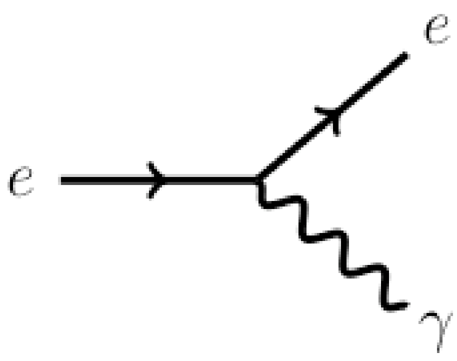




Electromagnetic showers

- When a high-energy e or γ enters an absorber, it initiates an em cascade as pair production and bremsstrahlung generate more e and γ with lower energy
- The ionization loss becomes dominant < a critical energy E_c
  - E_c ~ 88 MeV in air, ~ (550/Z)MeV
    - Approximate scaling in $y = E/E_c$
  - The longitudinal development ~scales as the radiation length in the material: $t = x/Xo$ (~440 m in air at NTP)
  - The transverse development scales approximately with the Moliere radius R_M ~ (21 MeV/E_c) Xo
    - In average, only 10% of energy outside a cylinder w/ radius R_M
    - In air, R_M ~ 80 m; in water R_M ~ 9 cm
- Electrons/positrons lose energy by ionization during the cascade process
- Not a simple sequence: needs Monte Carlo calculations

QED HE processes: bremsstrahlung for electrons…

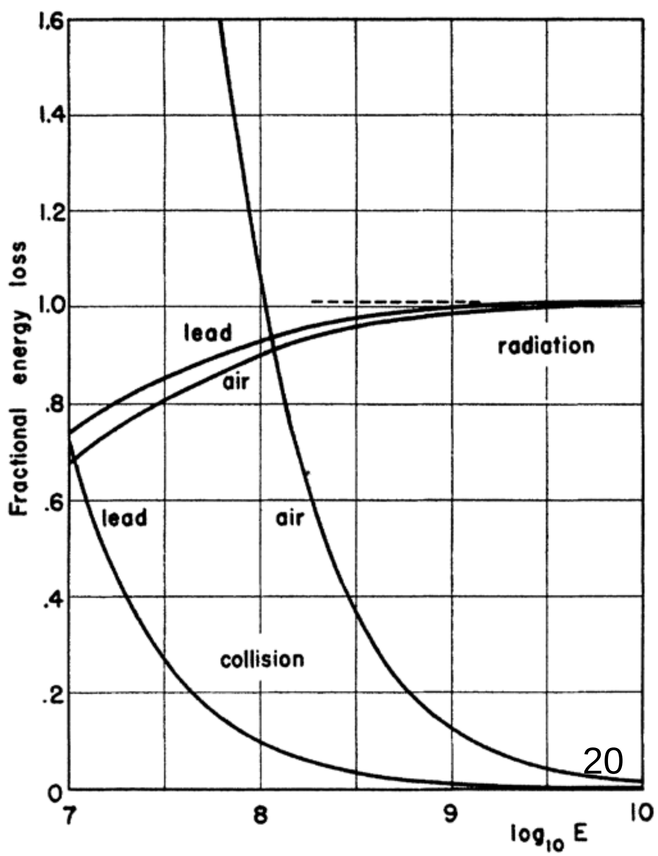


- (and pair production for photons). Forbidden in vacuo by 4-momentum conservation
  - Require interaction with the medium
- Bremsstrahlung (braking radiation): photons of momentum $q<E_e$ emitted with probability ~proportional to 1/q
  - (and collimated: ~ m_e/E)

  ie, energy emission is ~constant for each interval of photon energy; total is propto E
  - The dependence on the material appears through the radiation length Xo:

$$dE_e/dx = -1/X_o$$

  - Xo can be found in tables. It is ~440 m for air at NTP, ~43 cm for water; for density 1 g/cm^3 roughly proportional to A/Z^2
- Collision energy loss is almost constant (plateau)

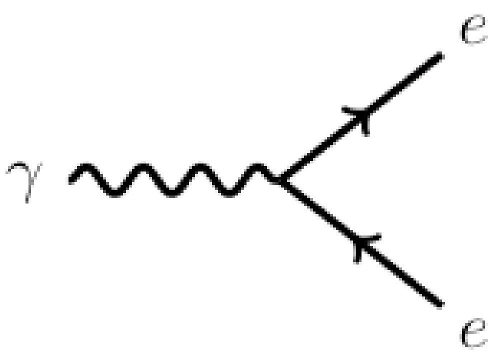


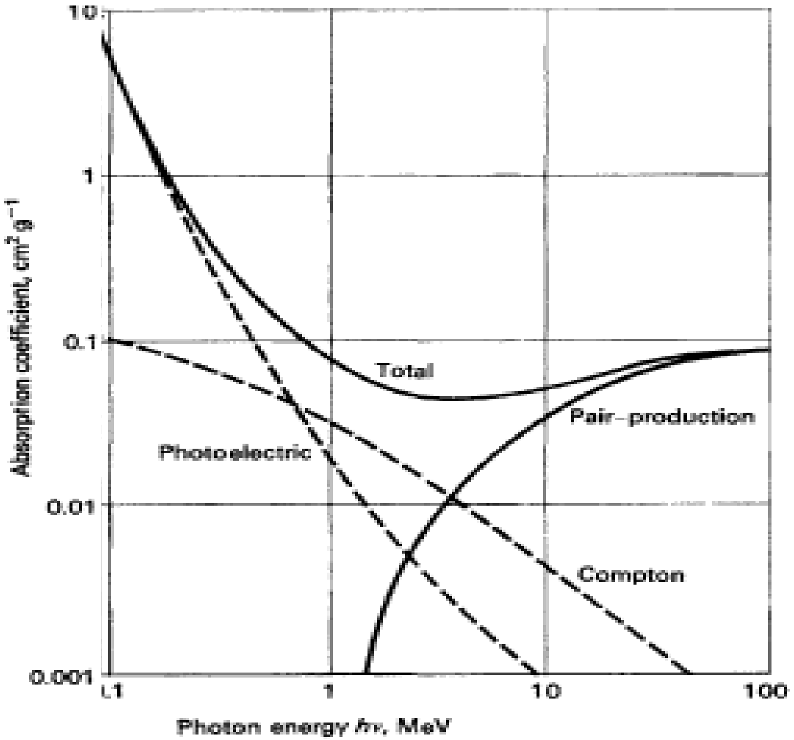
QED HE processes: …pair production for photons

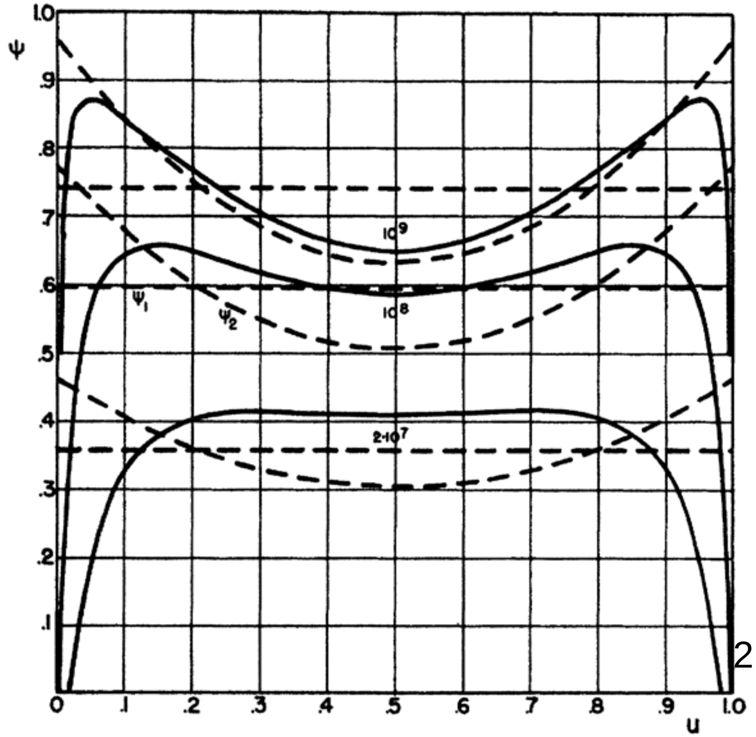
- Pair production:

  $\lambda = (9/7)\ Xo$ for $E\gamma >> 2m_e$

  Energy spectrum ~ flat







An analytic model: Rossi's "approximation B"

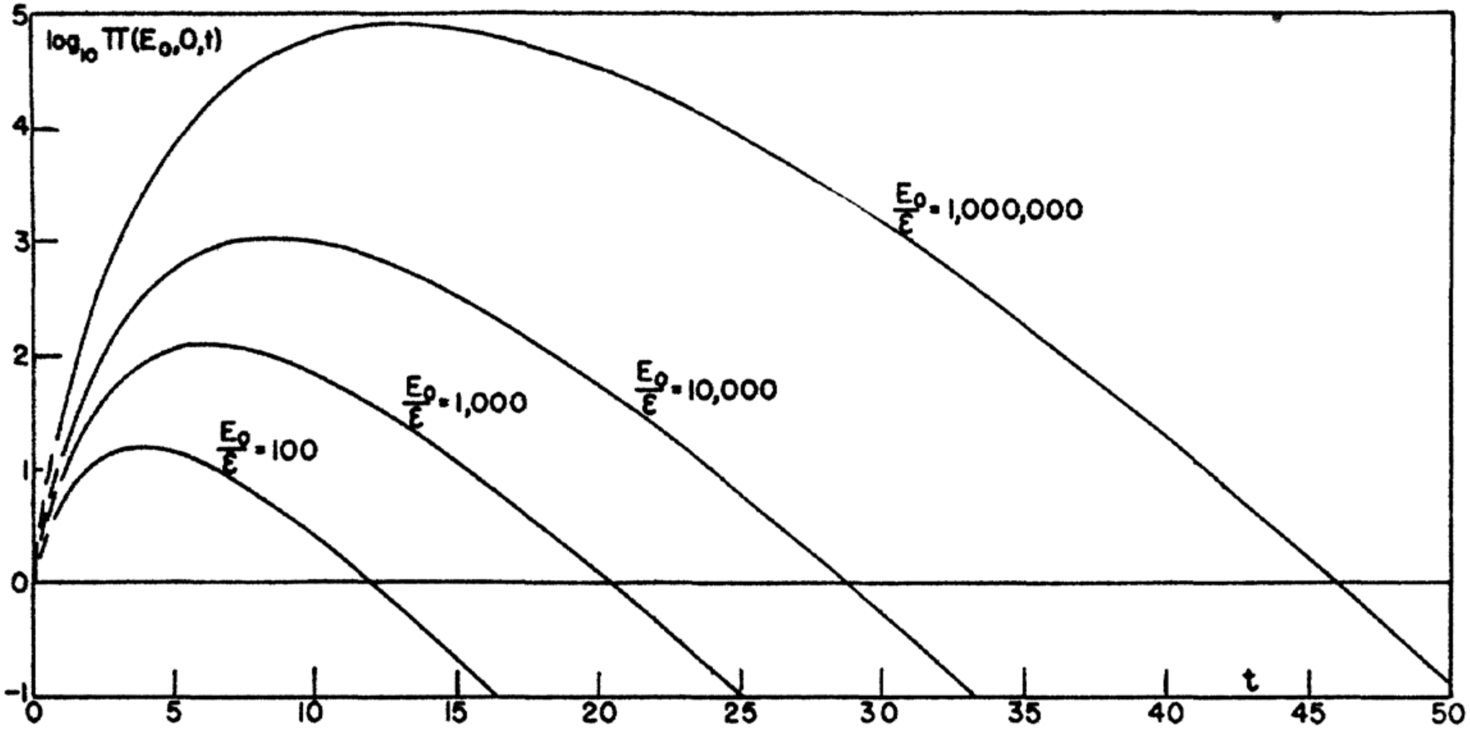
- Rossi in 1941 published an analytical formulation for the shower development as a set of 2 integro-differential equations under the approximation that:
  - Electrons lose energy by ionization & bremsstrahlung; asymptotic formulae hold
  - Photons undergo pair production only; asymptotic formulae hold ($E > 2\ m_e$)
- Very good approximation until $E \sim E_c$

	Incident electron	Incident photons
Peak of shower, t_{max}	$1.0 \times (\ln y - 1)$	$1.0 \times (\ln y - 0.5)$
Centre of gravity, t_{med}	$t_{max} + 1.4$	$t_{max} + 1.7$
Number e^+ and e^- at peak	$0.3\, y \times (\ln y - 0.37)^{-1/2}$	$0.3\, y \times (\ln y - 0.31)^{-1/2}$
Total track length T	y	y

A snapshot of Rossi's equations (you can solve them, but…)

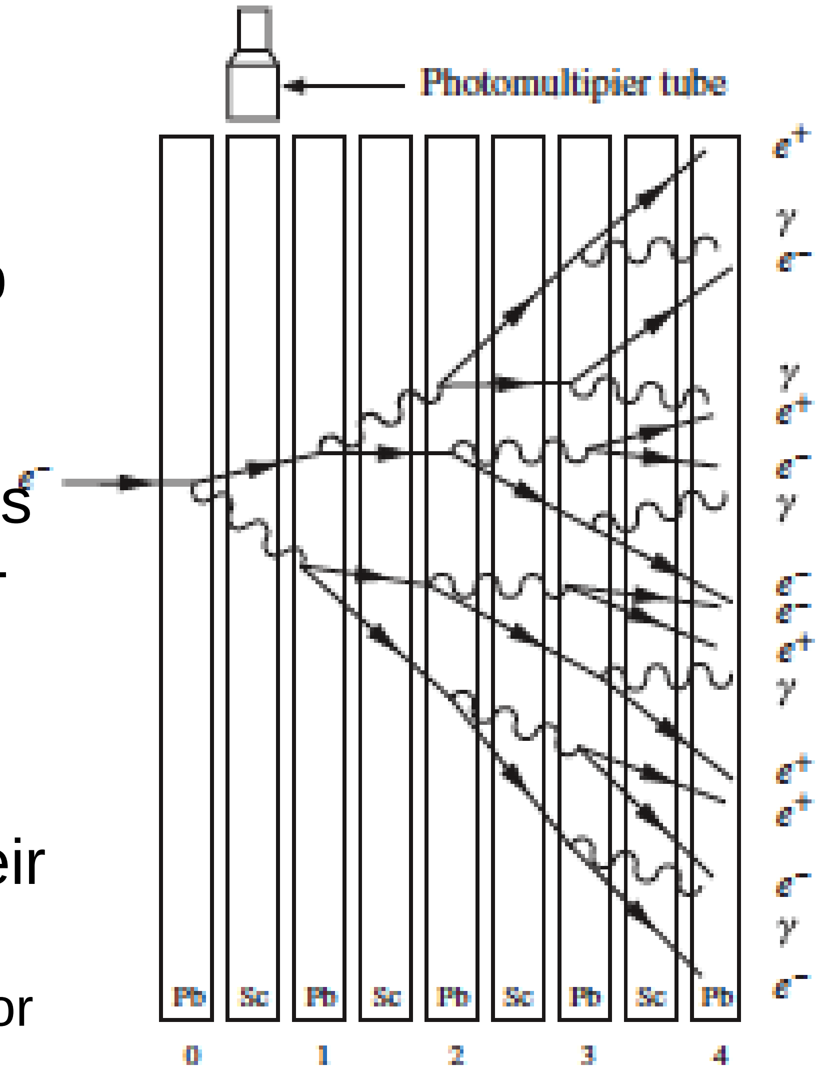
$$\frac{\partial \pi(E,t)}{\partial t} = 2\int_0^1 \gamma\left(\frac{E}{u},t\right)\psi_0(u)\frac{du}{u} - \int_0^1 \left[\pi(E,t) - \frac{1}{1-v}\pi\left(\frac{E}{1-v},t\right)\right]\varphi_0(v)dv + \epsilon\frac{\partial \pi(E,t)}{\partial E}$$

$$\frac{\partial \gamma(W,t)}{\partial t} = \int_0^1 \pi\left(\frac{W}{v},t\right)\varphi_0(v)\frac{dv}{v} - \sigma_0\gamma(W,t)$$



A simplified approach (Heitler)

- Qualitative features may be obtained from a simple model
  1. Each electron with $E>E_C$ travels 1 Xo and then gives up half of its energy to a bremsstrahlung photon
  2. Each photon with $E>E_C$ travels 1 Xo and then creates an e+e- pair with each particle taking E/2
  3. Electrons with $E<E_C$ cease to radiate and lose the rest of their energy by collisions
     - Ionization losses are negligible for $E>E_C$



Results from the simplified approach

- If the initial electron has energy $E_0 >> E_C$, after t Xo the shower will contain 2^t particles. ~equal numbers of e+, e-, γ, each with an average energy

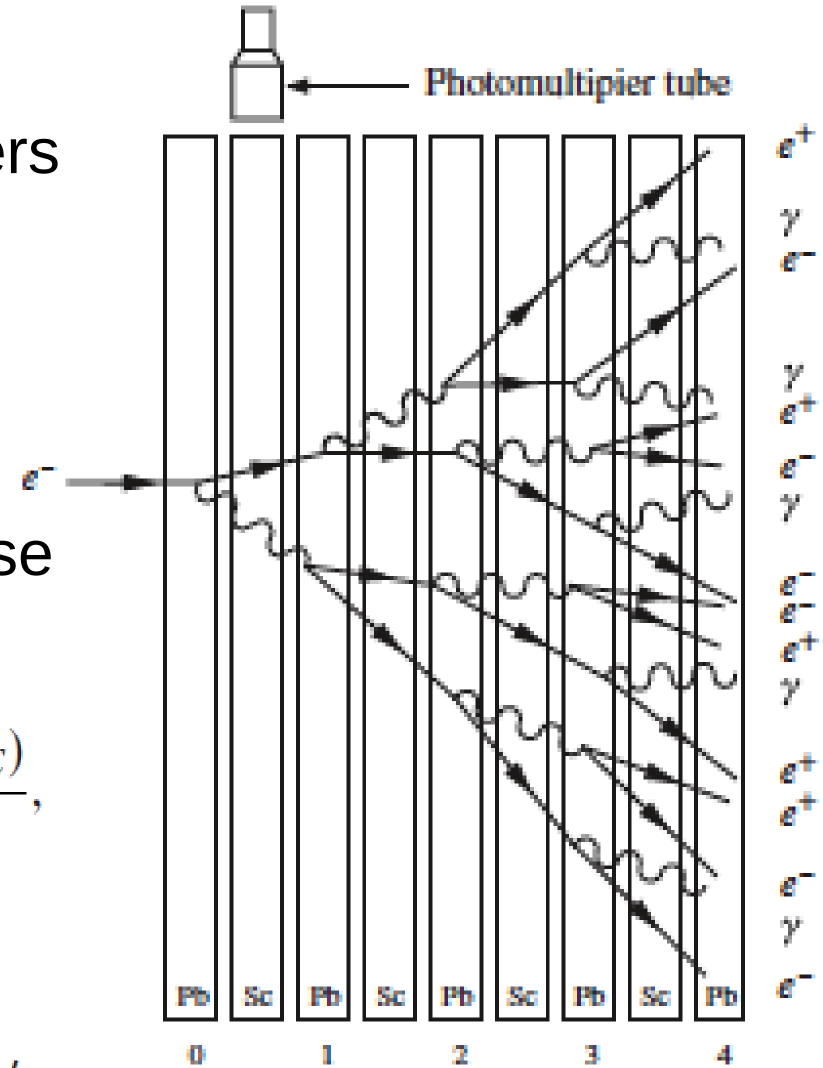
$$E(t) = E_0/2^t$$

- The multiplication process will cease when $E(t)=E_C$

$$t_{max} = t(E_C) \equiv \frac{\ln(E_0/E_C)}{\ln 2},$$

and the number of particles at this point will be

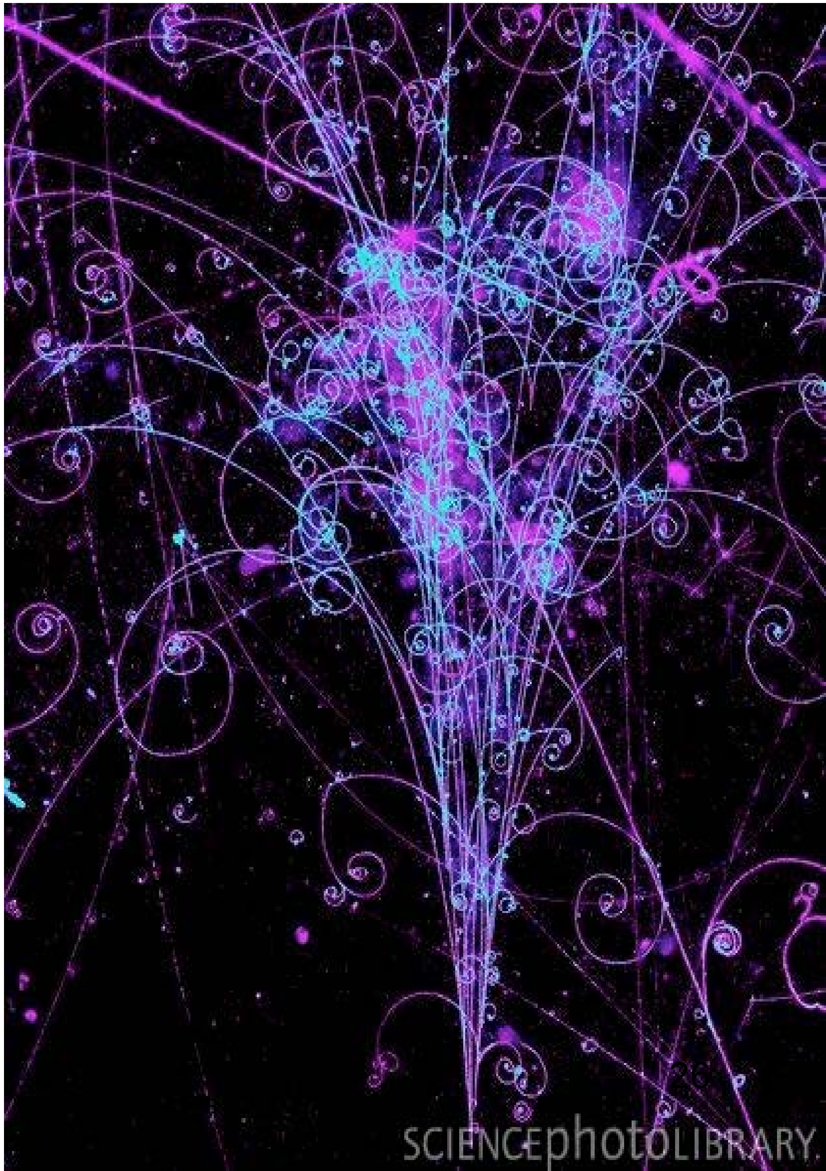
$$N_{max} = \exp(t_{max} \ln 2) = E_0 \big/ E_C$$



Energy measurement

– Errors asymptotically dominated by statistical fluctuations:

$$\frac{\sigma_E}{E} \cong \frac{k_E}{\sqrt{E}} \oplus c$$

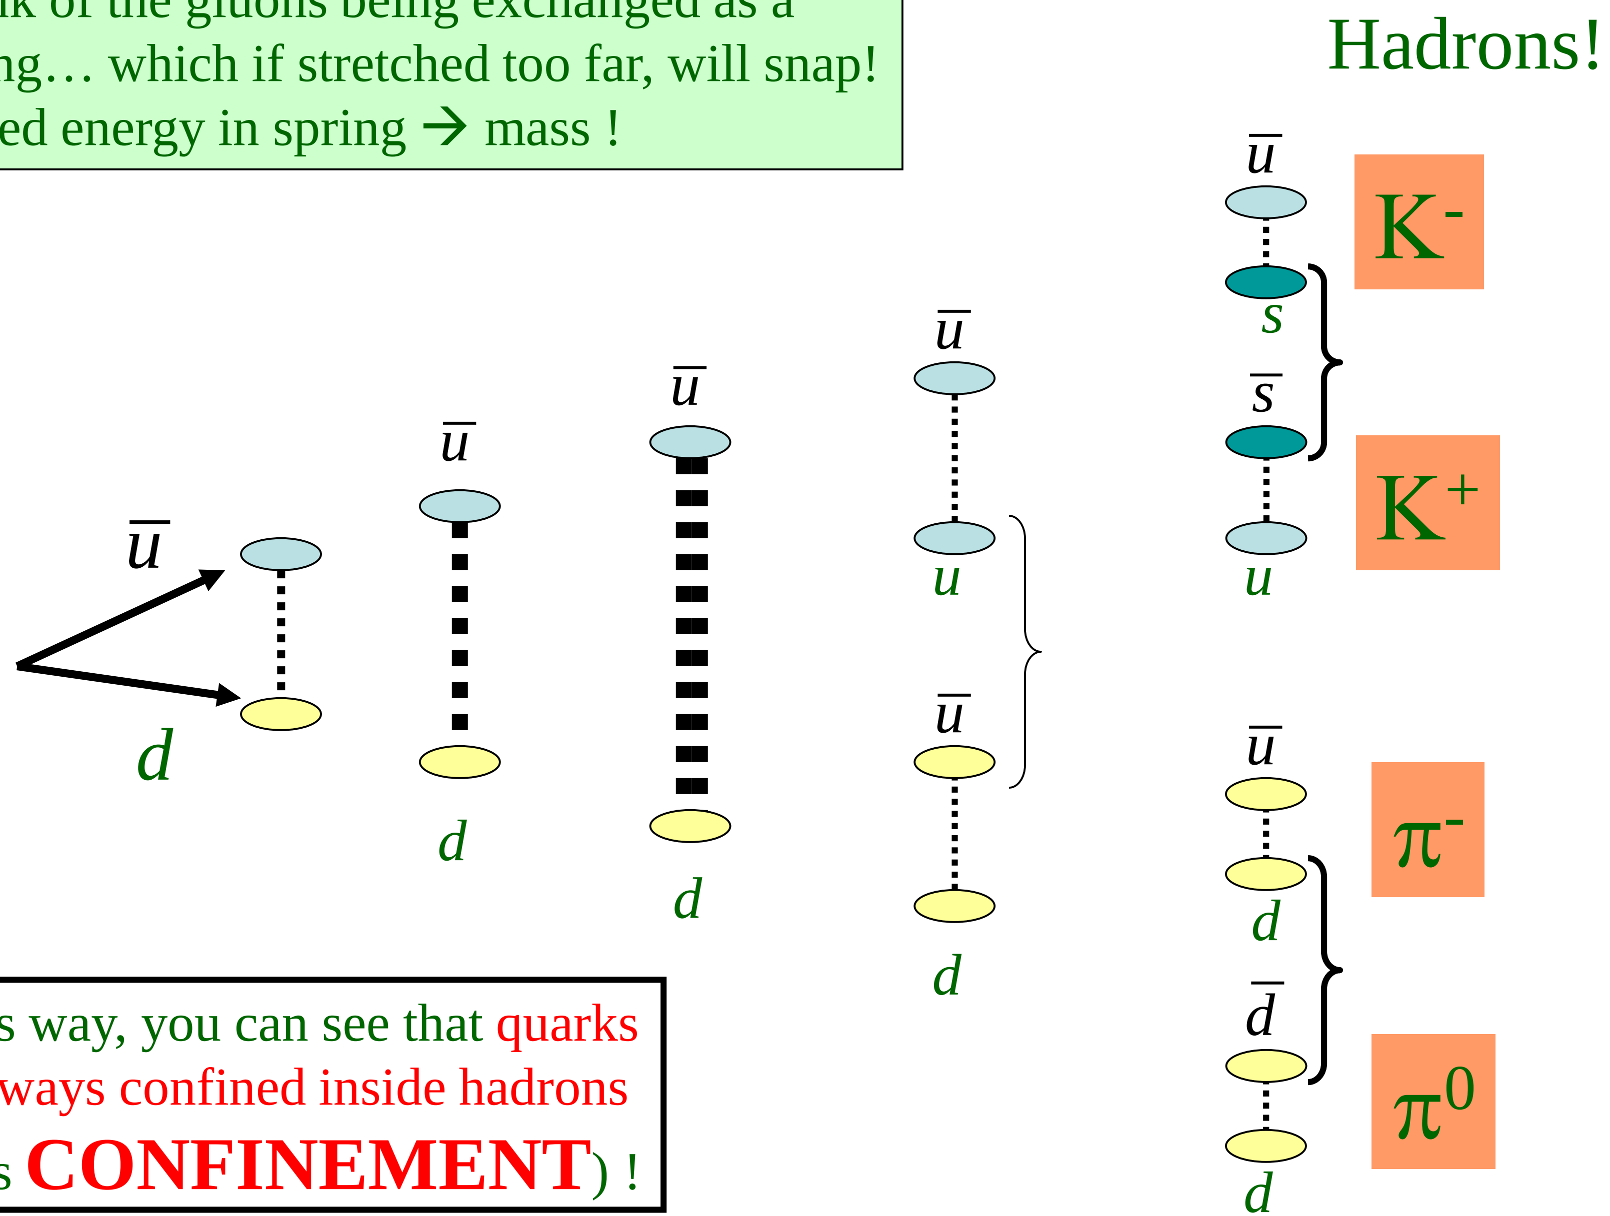


Hadronic showers

- Although hadronic showers are qualitatively similar to em, shower development is more complex because many different processes contribute
  - Larger fluctuations
- Some of the contributions to the total absorption may not give rise to an observable signal in the detector
  - Examples: nuclear excitation and leakage of secondary muons and neutrinos
- Depending on the proportion of π^0s produced in the early stages of the cascade, the shower may develop predominantly as an electromagnetic one because of the decay $\pi^0 \rightarrow \gamma\ \gamma$
- The scale of the shower is determined by the nuclear absorption length λ_H
  - Typically $\lambda_H > X_o$
  - Larger lateral width

String fragmentation

Think of the gluons being exchanged as a spring… which if stretched too far, will snap! Stored energy in spring → mass !



In this way, you can see that quarks are always confined inside hadrons (that's **CONFINEMENT**) !

Neutrino interactions: no interaction in space; with Earth

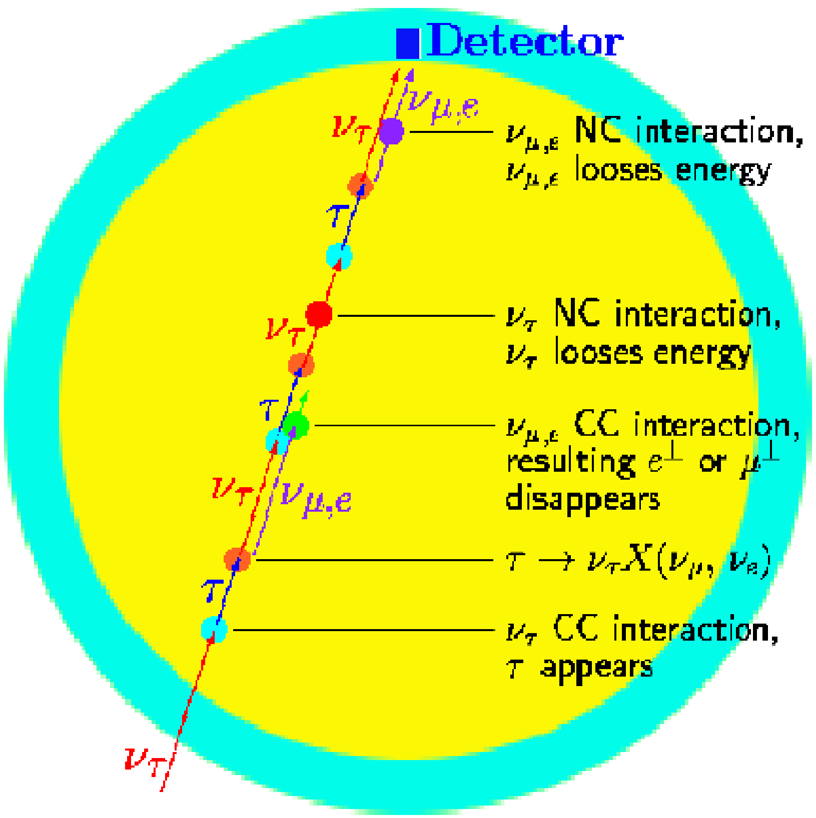
$\sigma_\nu \nearrow E_\nu$

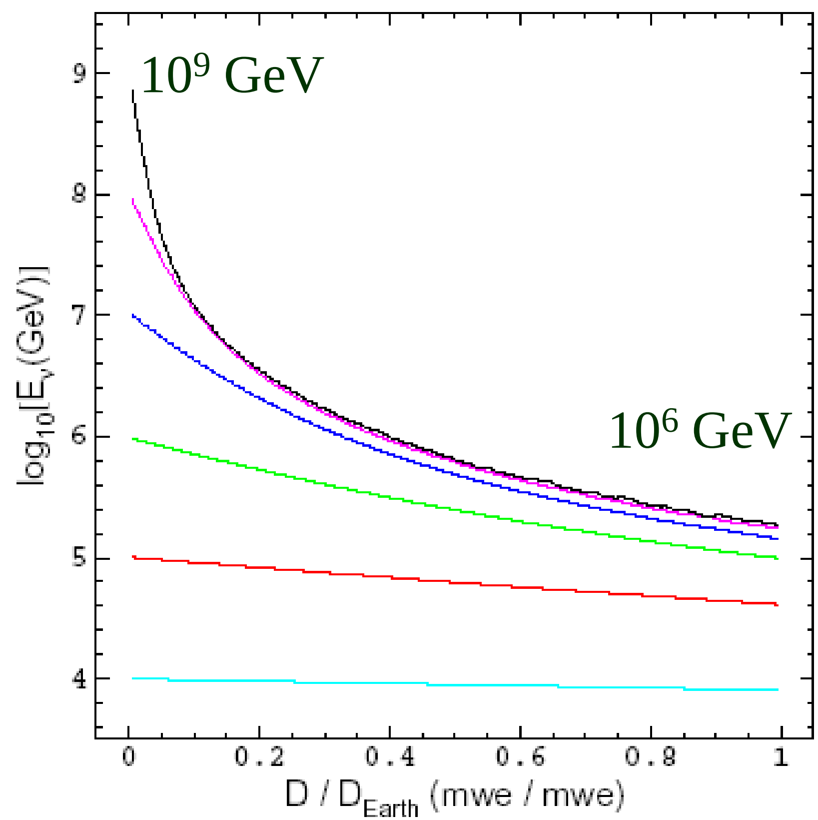
$\nu_\tau \rightarrow \tau \rightarrow \nu_\tau \rightarrow \ \ldots$

ν_τ energy degradation

The Earth is opaque to ν_e ν_μ

Above $E_\tau \sim 10^7$ GeV: $L_{\tau int} < L_{\tau decay}$





Fraction of Earth diameter

Calorimeter (CAL)

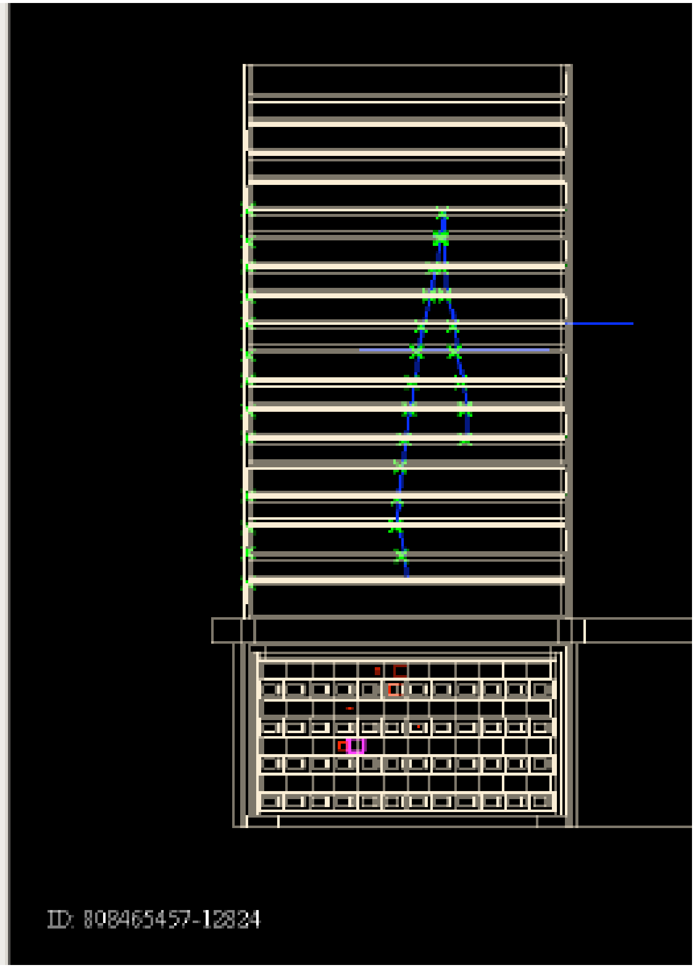
Array of 1536 CsI(Tl) crystals in 8 layers

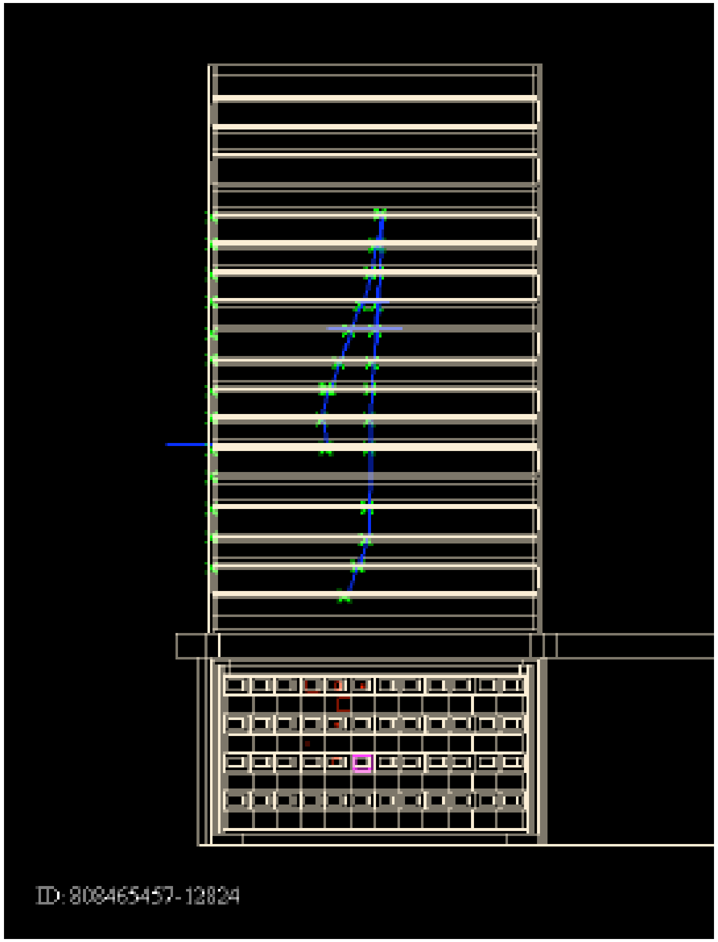
Measurement of the electron energy

The Silicon tracker is mainly built in Italy

Italy is also responsible for the detector simulation, event display and GRB physics

Detection of a gamma-ray





Ground-based telescopes still needed for VHE…

- Peak eff. area of Fermi: 0.8 m^2

  From strongest flare ever recorde of very high energy (VHE) γ-rays:

  1 photon / m^2 in 8 h above 200 GeV

  (PKS 2155, July 2006)

- The strongest *steady* sources are > 1 order of magnitude weaker!
- Besides: calorimeter depth $\leq 10\ X_0$

$\Rightarrow$ VHE astrophysics (in the energy region above 100 GeV) can be done only at ground

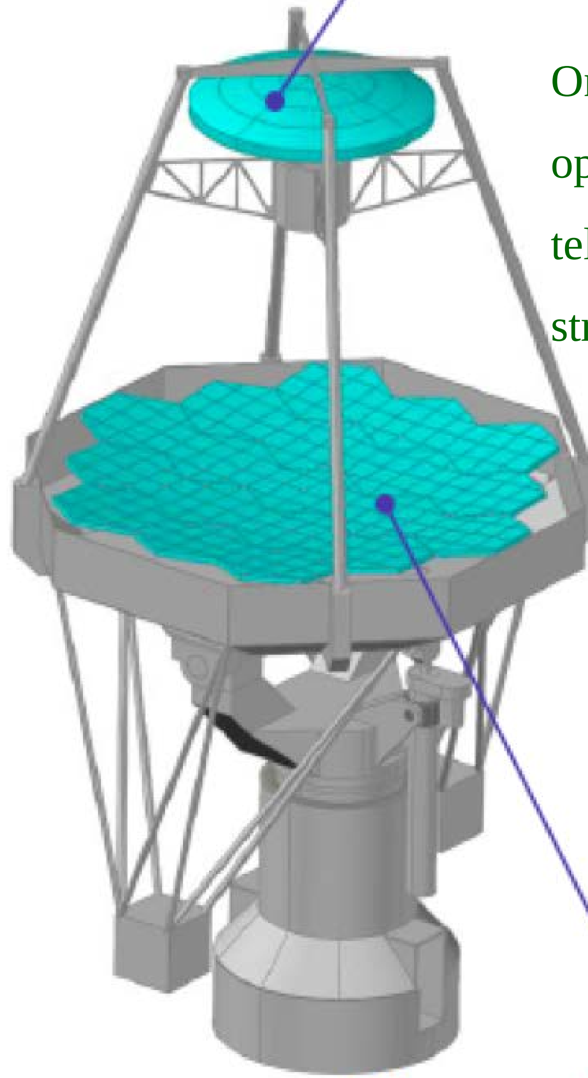
single-mirror optics

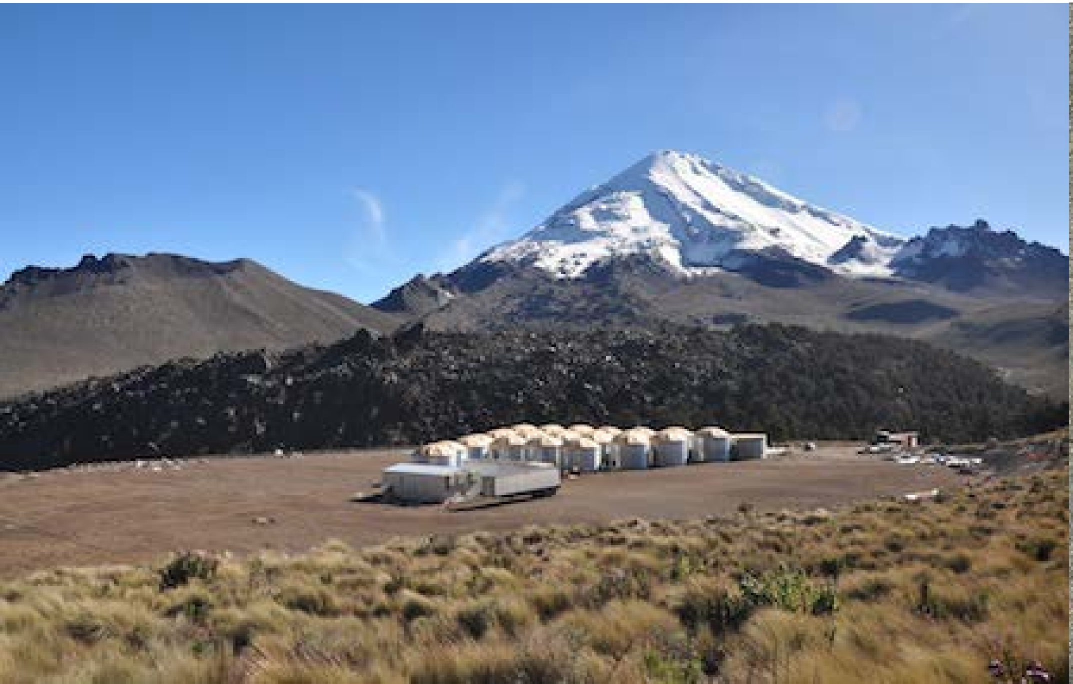
PMT-based and silicon-based sensors

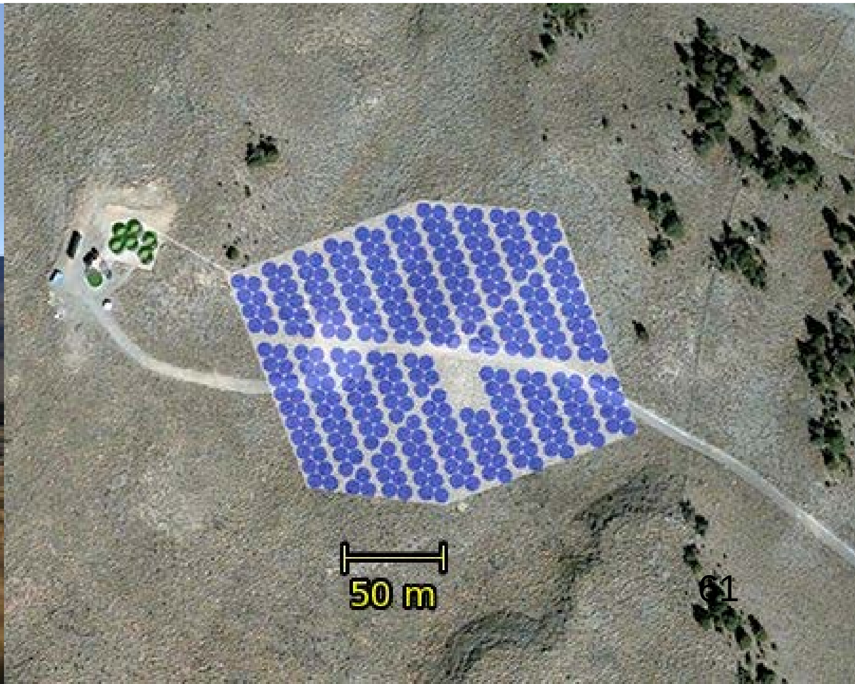
→ Not yet conclusive which solution is most cost-effective



Future in EAS detectors: HAWC

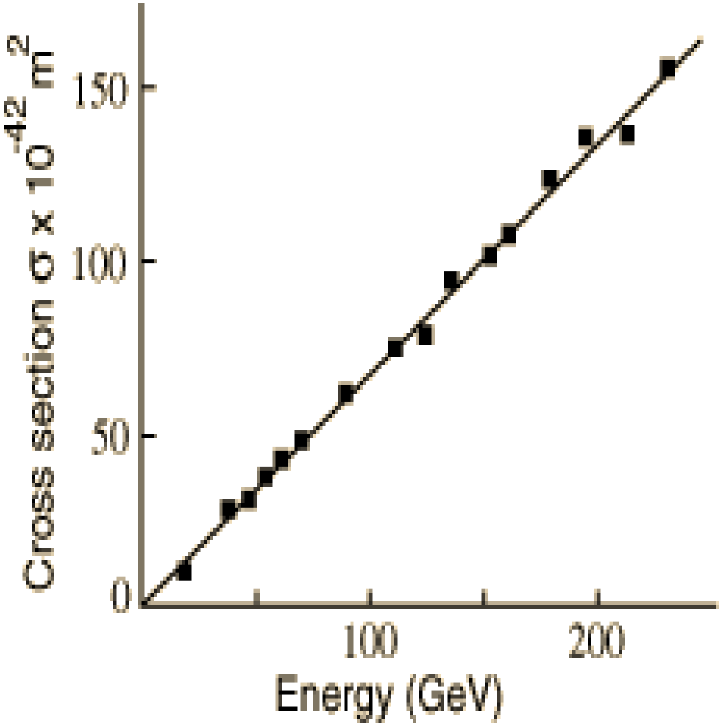
- EAS detectors have advantages on Cherenkov: duty cycle, serendipitous searches
- But the EAS up to now (Argo, Milagro, Tibet) were not sensitive enough
- The High-Altitude Water Cherenkov Observatory, or HAWC, is a facility designed to observe TeV gamma rays and cosmic rays with large FOV, with sensitivity better than 10% Crab in 1 year between 200 GeV and 100 TeV
- HAWC is under construction at 4100 m asl in Mexico





Neutrino detection

- Since cross section is small, needs large converters (and large detection volumes)
  - Use the Earth as converter
  - Make Cherenkov detectors using as fluids the sea and the Antarctica ices



IceCube / Deep Core

- 5160 optical sensors between 1.5 ~ 2.5 km
- detects > 200 neutrino-induced muons and ~ 2 x10^8 cosmic ray muons per day

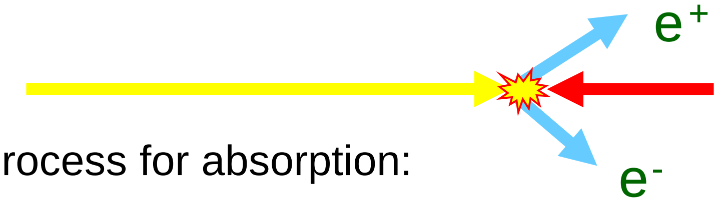
PARIS, LE 1ER JUILLET 1953

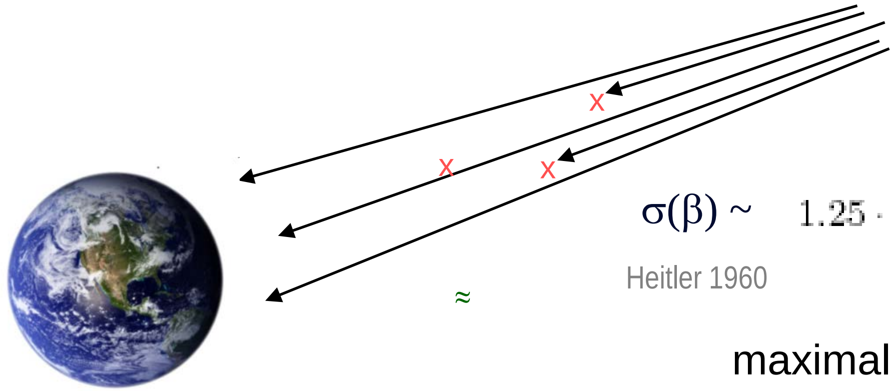
Questions on Cosmic Rays

- CR at 100 TeV x 10 come from SNR; still >1 decade from the knee…
- Are the other galactic sources of gamma rays important for the formation of CR?
  - Binaries accreting galactic BH
  - ...
  - Pulsars and electron-positron pairs
- How are CR accelerated in AGN?
- Are they accelerated also in GRB?

(Need improvement of energy range, PSF, stat)

Propagation of γ-rays





dominant process for absorption:

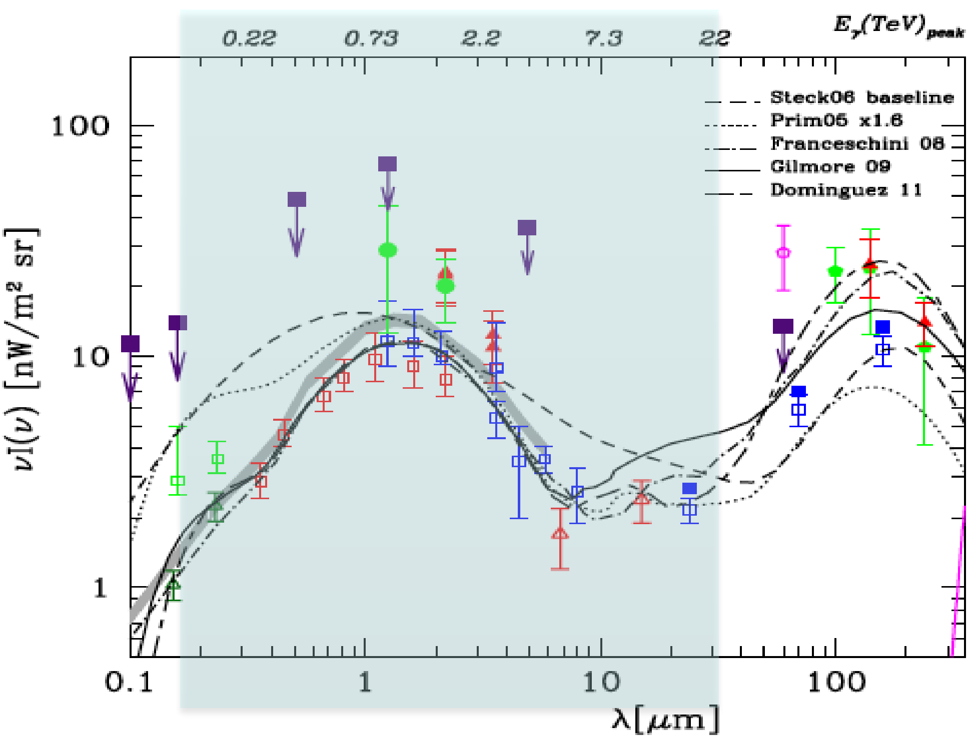
$$\gamma_{VHE}\gamma_{bck} \rightarrow e^+e^-$$

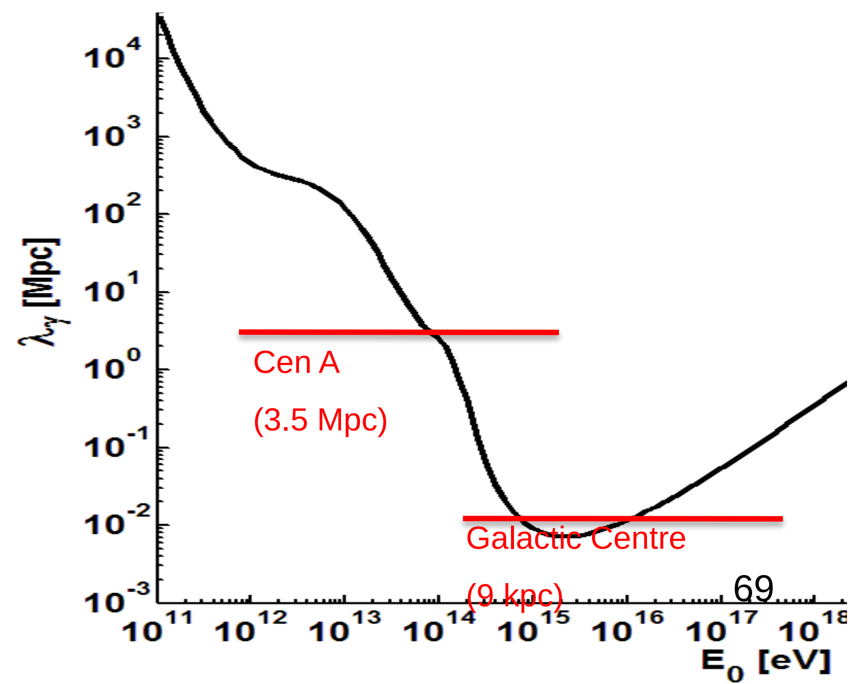
$$\sigma(\beta) \sim \quad 1.25 \cdot 10^{-25}(1-\beta^2) \cdot \left[2\beta(\beta^2-2) + (3-\beta^4)\ln\left(\frac{1+\beta}{1-\beta}\right)\right] \mathrm{cm}^2$$

Heitler 1960

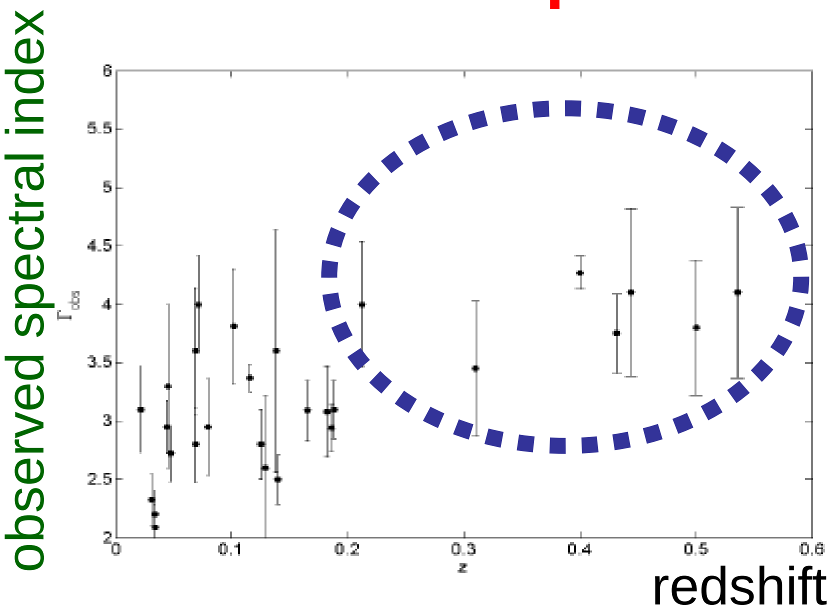
maximal for: $$\boxed{\epsilon \simeq \frac{2m_e^2c^4}{E} \simeq \left(\frac{500\ \mathrm{GeV}}{E}\right) \mathrm{eV}}$$

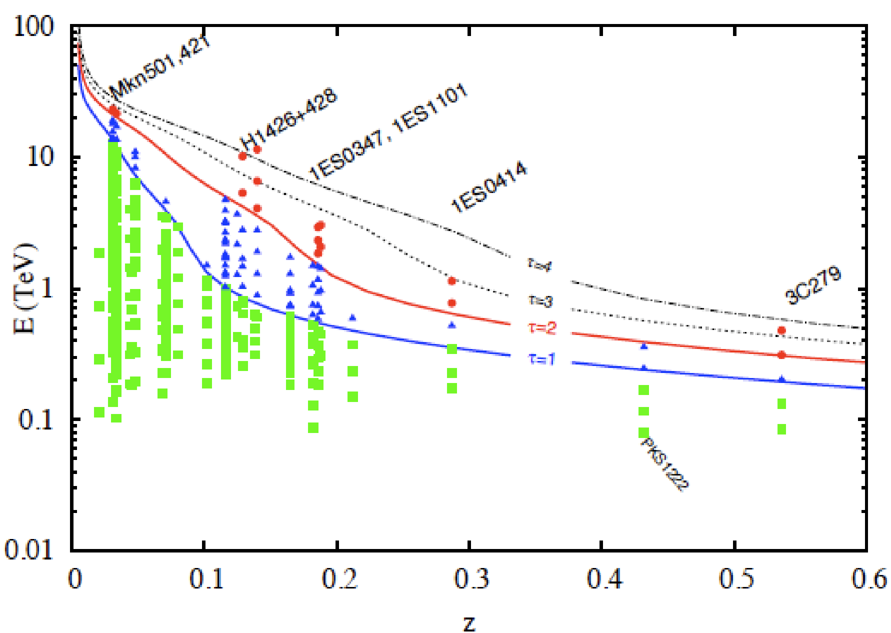
- For gamma rays, relevant background component is optical/infrared (EBL)
- different models for EBL: minimum density given by cosmology/star formation





If there is a problem





Explanations from the standard ones

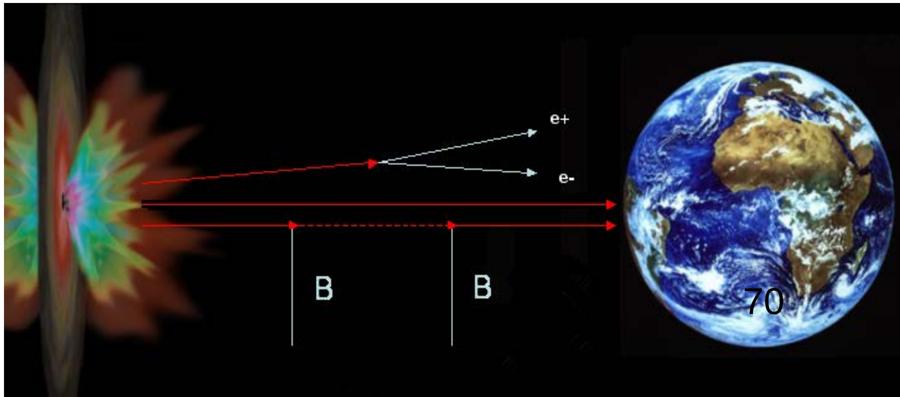
- very hard emission mechanisms with intrinsic slope < 1.5 (Stecker 2008)
- Very low EBL, plus observational bias, plus a couple of "wrong" outliers

to almost standard

- γ-ray fluxes enhanced by relatively nearby production by interactions of primary cosmic rays or ν from the same source

to possible evidence for new physics

- Oscillation to a light "axion"? (DA, Roncadelli & MAnsutti [DARMA], PRD2007, PLB2008)
- Axion emission (Simet+, PRD2008)
- A combination of the above (Sanchez Conde et al. PRD 2009)



Moving to very fancy explanations of unexpected results on the transparency of the Universe

- Emission models are more complicated than we think (but only for sources far away: nearby sources behave well)

- VHE photons are generated on the way (interaction of cosmic rays, neutrinos and photons with intergalactic medium: Sigl, Essey, Kusenko, …)

- Something is wrong in the $\gamma\gamma$ -> e+e- rate calculation
  - Vacuum energy (new sterile particles coupling to the photons): DARMA, …
    - For example an ALP: consistent values for m, g=(1/M) in a range not experimentally excluded (“Se non e’ vero e’ ben pensato”)
  - $\gamma\gamma$ -> e+e- cross section

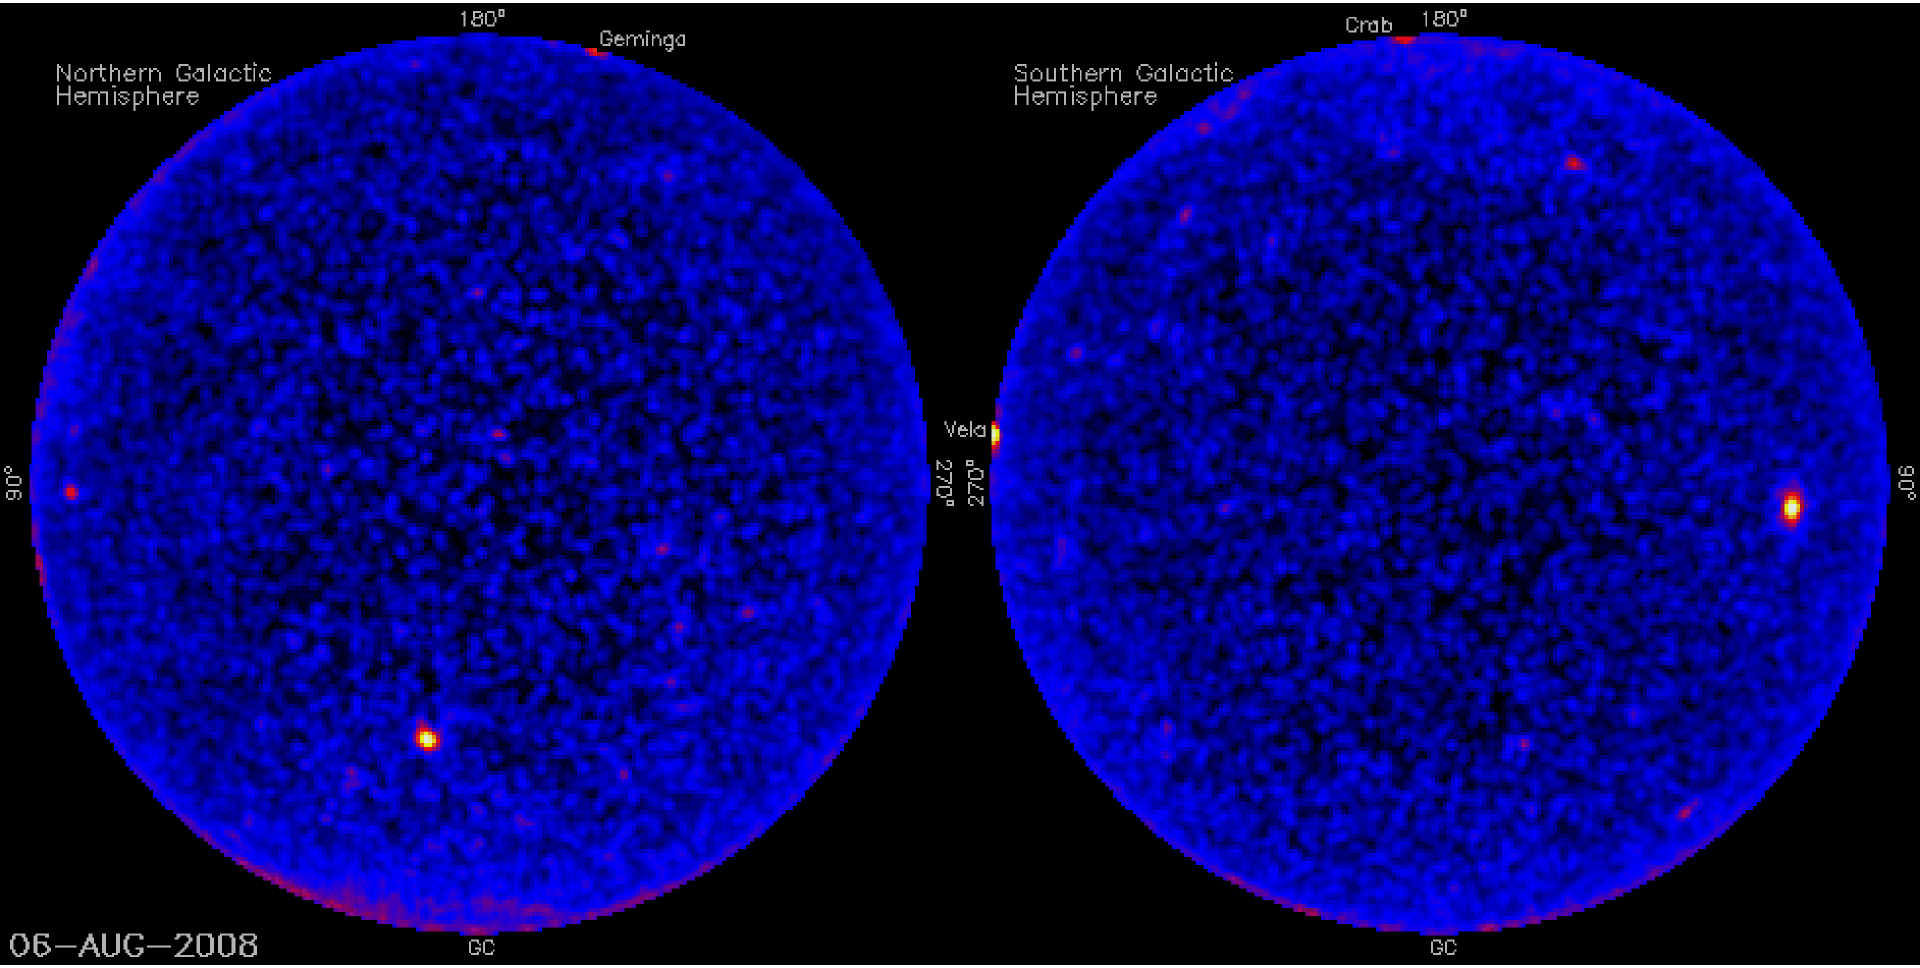
    QED calculations appears to be in a safe region; then it must be
    - the boost (Lorentz transformations; relativity)

Is Lorentz invariance exact?
Due to large E, d astroparticles are a crash test

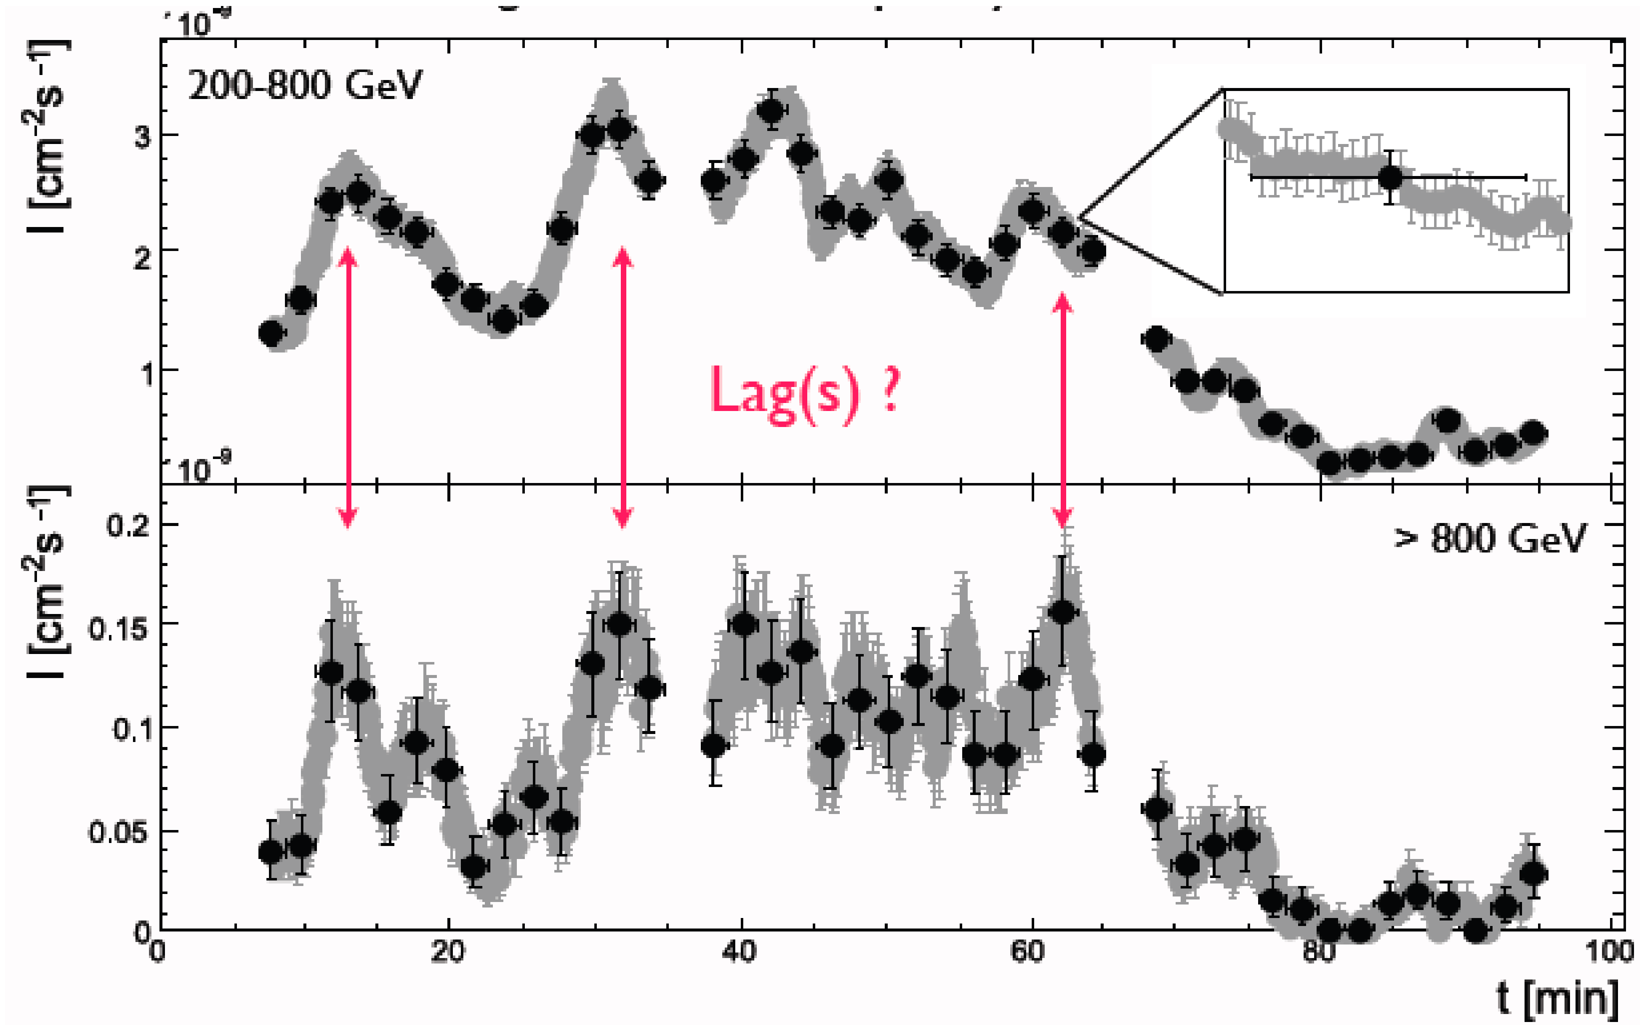
- For longtime violating Lorentz invariance/Lorentz transformations/Einstein relativity was a heresy
  - Is there an aether? (Dirac 1951)
  - Many preprints, often unpublished (=refused) in the ’90s
    - Gonzales-Mestres, ADA, Jacobson, …

- Then the discussion was open
  - Trans-GZK events? (AGASA collaboration 1997-8)
  - LIV => high energy threshold phenomena: photon decay, vacuum Cherenkov, GZK cutoff (Coleman & Glashow 1997-8)
  - GRB and photon dispersion (Amelino-Camelia et al. 1997)
  - Framework for the violation (Colladay & Kostelecky 1998)
  - LIV and gamma-ray horizon (Kifune 1999)
  - …

Variability



Tests of Lorentz violation: the name of the game

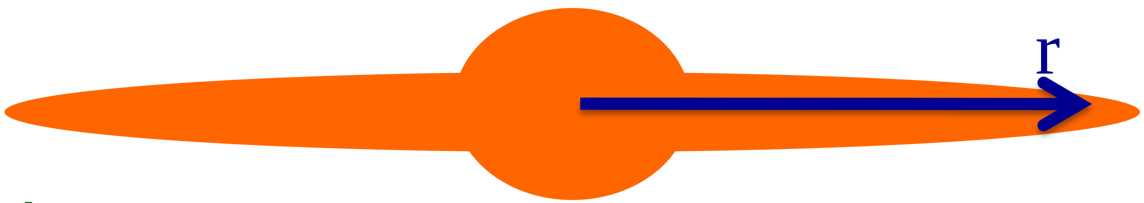


No signal uo to now, ~Mp

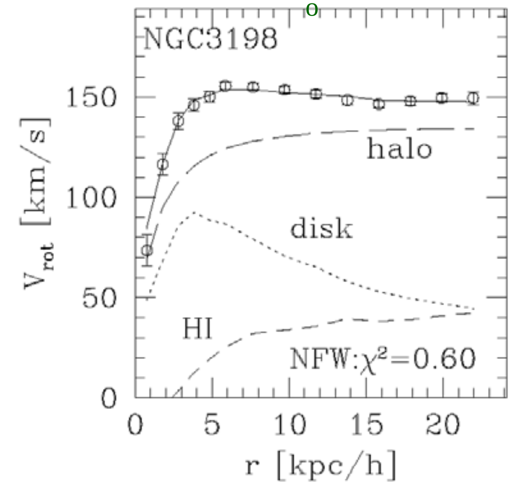
HESS, PKS 2155

The Dark Matter Problem

Measure rotation curves for galaxies:



Begelman/Navarro

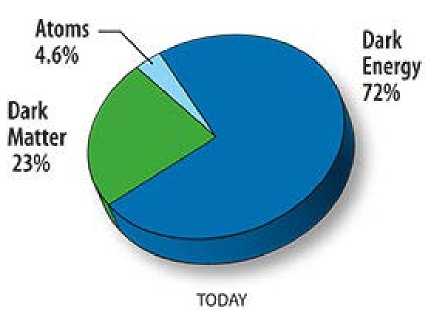


For large r, we expect:

$$G\frac{M}{r^2} = \frac{v^2(r)}{r} \quad \Rightarrow \quad v(r) \sim \frac{1}{\sqrt{r}}$$

we see: flat or rising rotation curves

Hypothesized solution: the visible galaxy is embedded in a much larger halo of Dark Matter (neutral; weakly interacting; mix of particles and antiparticles - in SUSY Majorana)



Famous

Bullet Cluster

(B. Atwood)

Which signatures for gamma detectors?

- Self-annihilating WIMPs, if Majorana (as the neutralino in SUSY), can produce:
  - Photon lines ($\gamma\gamma$, γZ)
  - Photon excess at E < m from hadronization
- Excess of antimatter (annihilation/decay)
- Excess of electrons, if unstable

$$\Phi \propto \sigma \frac{\langle v \rangle}{m^2} \int_{los} \rho^2 \, dl$$
