XIV. Data Analysis and Particle Physics

- ~2 scientists in 1country
- Pen and paper

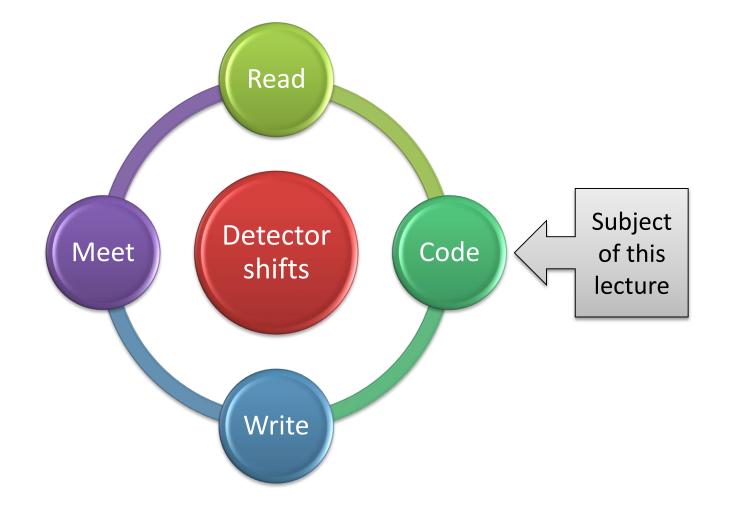

- ~200 scientists in ~10 countries
- Mainframes, supercomputers

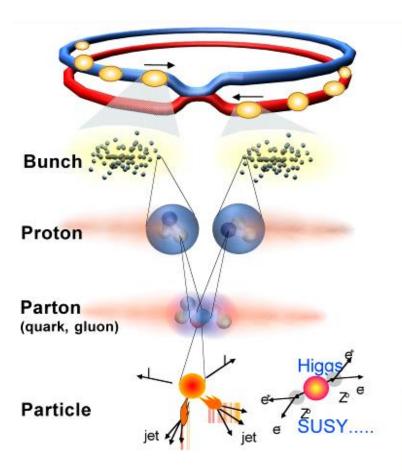

A discovery at LHC

- ~2000 scientists in ~100 countries
- Computing and data grids

A typical LHC physicist's workflow today

Collisions at the LHC

Proton-Proton	2835 bunch/beam
Protons/bunch	10 ¹¹
Beam energy	7 TeV (7x10 ¹² eV)
Luminosity	10 ³⁴ cm ⁻² s ⁻¹

Crossing rate 40 MHz

Collisions rate $\approx 10^7 - 10^9$ Hz

Event selection: 1 in 10,000,000,000,000

Modern HEP* data processing workflow

All analysis and simulation software in Particle Physics is written by physicists
 Free and usually Open Source or Public Domain code

* HEP: High Energy Physics, a.k.a. Particle Physics

Event generators

- Also known as Monte Carlo
- Are complex software programs that implement our current knowledge of physics
 - Based on the Standard Model
 - Hadronisation (soft QCD) is up to different phenomenological models
 - Allow programmatic inclusion of various processes beyond the Standard Model
 - Are not always exact: precise quantum mechanic effects evaluation may take too much computational resources
- There are many Monte Carlo generators on the market
 - Use different phenomenological models
 - Some are <u>tuned</u> to or specialised in different processes
 - <u>None</u> has true predictive power, though some are better than others
 - <u>Need experimental data</u> for tuning, have many free parameters
 - All written by physicists for physicists
 - Top favorite: **Pythia** (made in Lund)

Why is it called Monte Carlo?

In general, "Monte Carlo" term refers to any numerical method that makes use of random numbers in order to simulate probabilistic processes

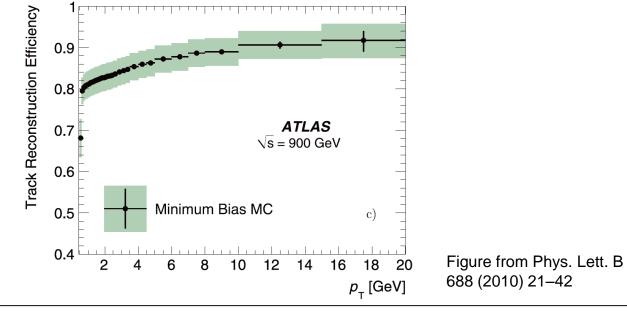

- Substitution of the second second
- Quantum mechanics: amplitudes \Rightarrow probabilities
- Anything that possibly can happen, will! (but more or less often)

Slide adapted from Torbjörn Sjöstrand

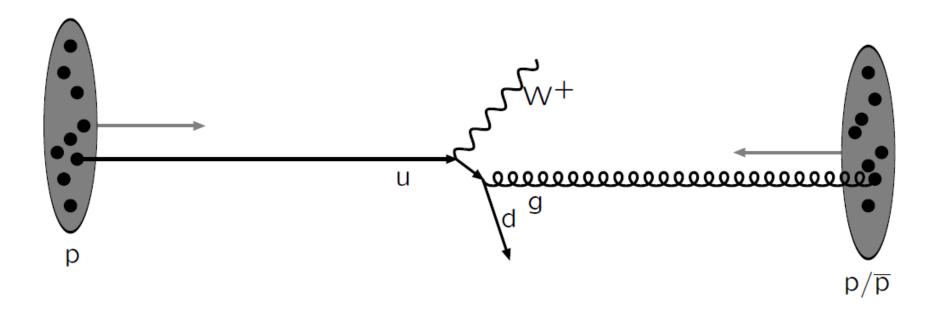

Why do we need Monte Carlo?

- To design new experiments and plan for new searches
 - Any new theory can be coded and plugged into a Monte Carlo generator
- To identify unexpected experimental signal
 - When Monte Carlo prediction does not correspond to experimental data, it <u>may</u> mean we see an unexplained phenomenon (or there is a bug in the program)
- To correct for detector inefficiencies

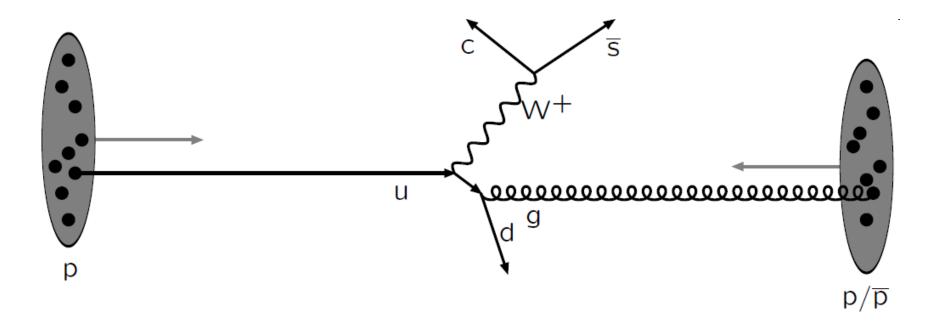

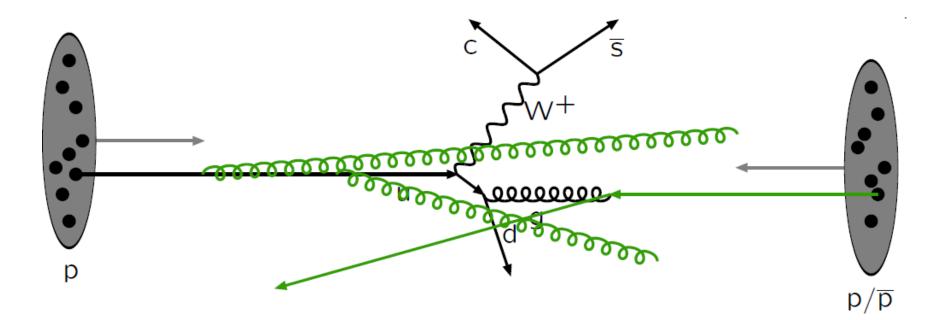

Incoming beams: parton densities

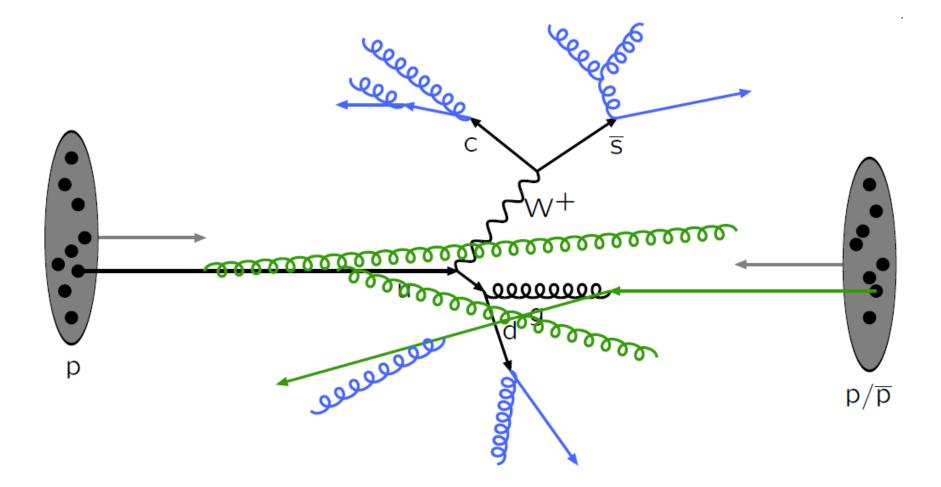

Hard subprocess: described by matrix elements

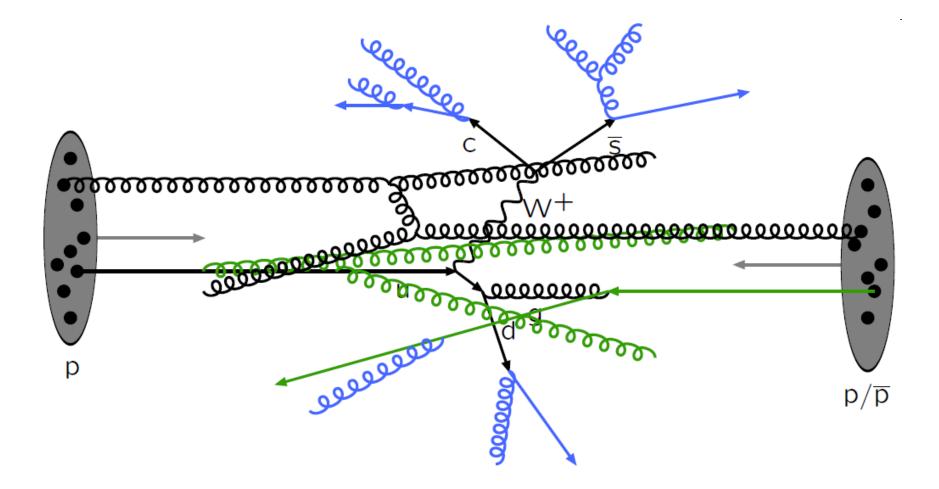

Resonance decays: correlated with hard subprocess

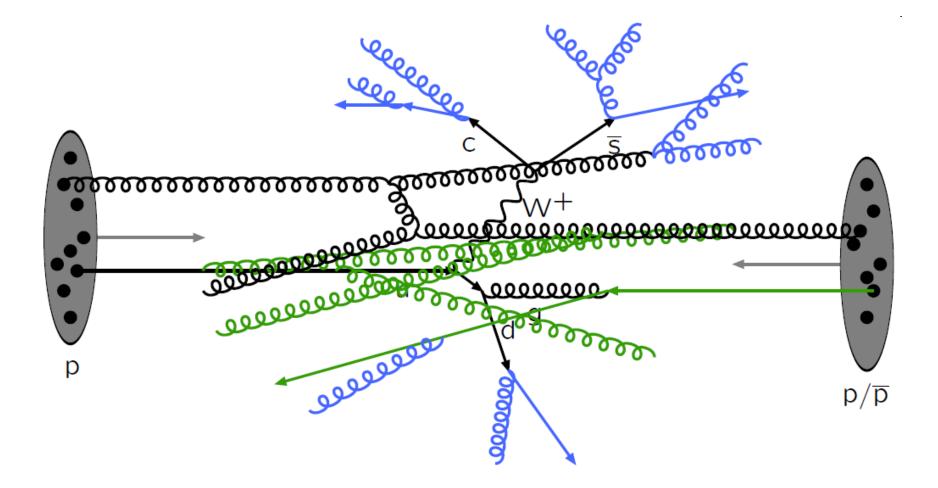

Initial-state radiation: spacelike parton showers

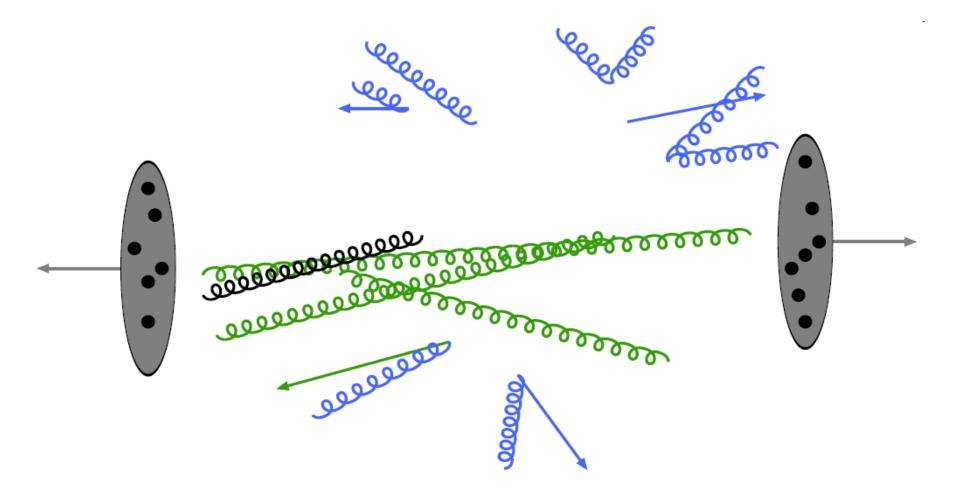

Final-state radiation: time-like parton showers

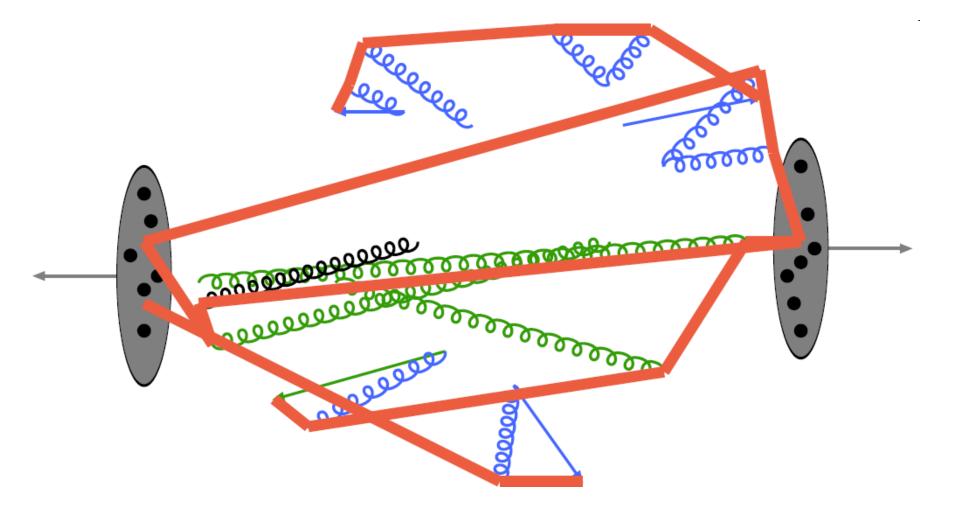

Multiple parton-parton interactions...

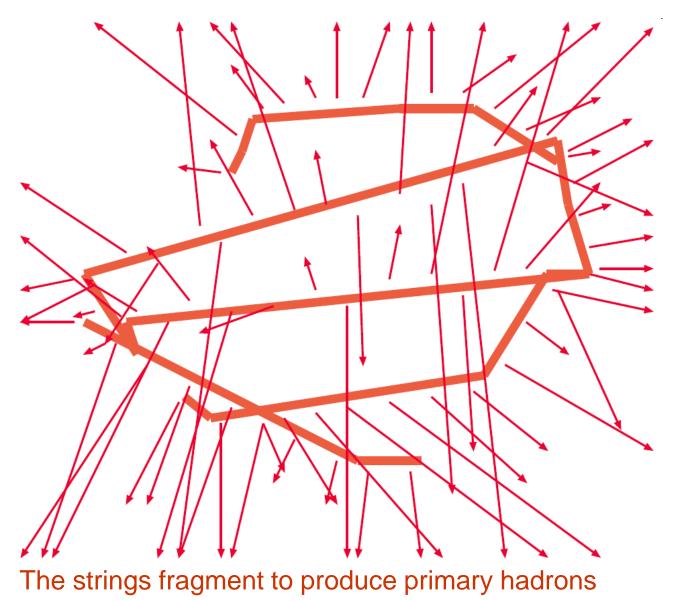

... with its initial- and final-state radiation

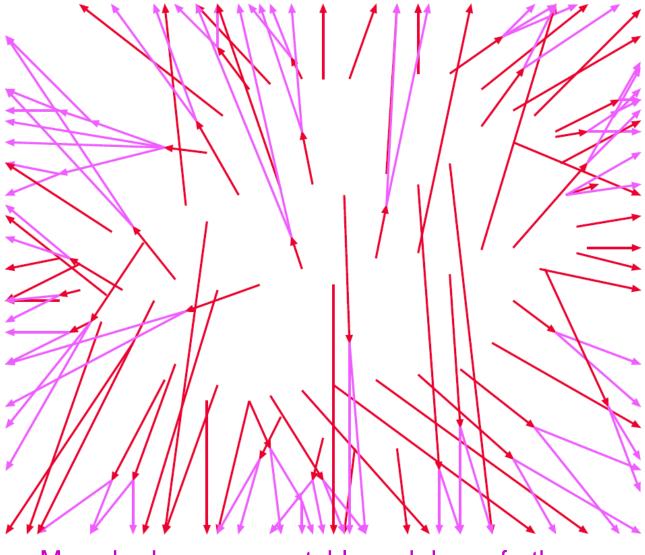

Beam remnants and other outgoing partons

Everything is connected by colour confinement strings

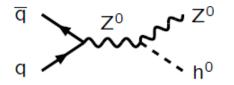

Many hadrons are unstable and decay further

Event physics overview

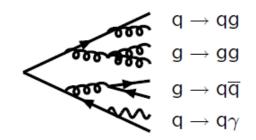

Matrix elements (ME):

1) Hard subprocess: $|\mathcal{M}|^2$, Breit-Wigners, parton densities.

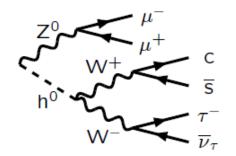

Parton Showers (PS):

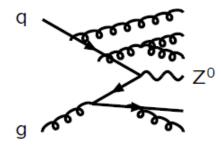

3) Final-state parton showers.

2) Resonance decays: includes correlations.

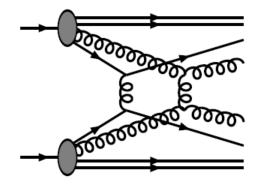

4) Initial-state parton showers.

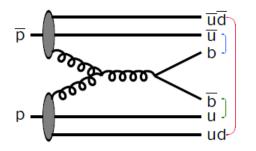

Event physics overview

5) Multiple parton–parton interactions.

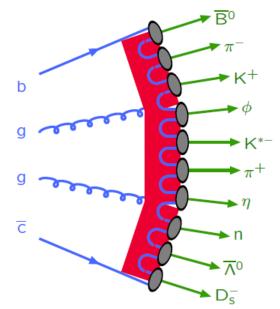

6) Beam remnants, with colour connections.

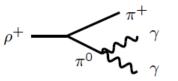

5) + 6) = Underlying Event

7) Hadronization

8) Ordinary decays: hadronic, τ , charm, ...

Pythia – describes data best

- Pythia was known as the Oracle of Delfi, possessed immense predictive powers (until year 393)
- In 21st century, Pythia is arguably the most successful HEP Monte Carlo generator

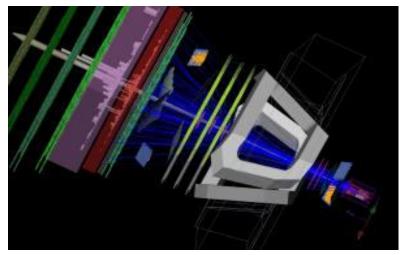

- Pythia highlights:
 - Hard processes: Standard Model and beyond, resonance decays etc
 - Showers: initial- and final-state radiation, transverse momentum ordered
 - Underlying event: multiple interactions, colour-connected beam remnants
 - Hadronisation: Lund model, particle decays, Bose-Einstein effects
 - Various auxiliary utilities

Simplest code using Pythia 8 (C++)

```
// File: main01.cc. The charged multiplicity distribution at the LHC.
#include "Pythia.h"
using namespace Pythia8;
int main() {
 // Generator. Process selection. LHC initialization. Histogram.
  Pythia pythia;
  pythia.readString("HardQCD:all = on");
  pythia.readString("PhaseSpace:pTHatMin = 20.");
  pythia.init( 2212, 2212, 14000.);
  Hist mult("charged multiplicity", 100, -0.5, 799.5);
  // Begin event loop. Generate event. Skip if error. List first one.
  for (int iEvent = 0; iEvent < 100; ++iEvent) {</pre>
    if (!pythia.next()) continue;
    if (iEvent < 1) {pythia.info.list(); pythia.event.list();}</pre>
    // Find number of all final charged particles and fill histogram.
    int nCharged = 0;
    for (int i = 0; i < pythia.event.size(); ++i)</pre>
      if (pythia.event[i].isFinal() && pythia.event[i].isCharged())
        ++nCharged;
    mult.fill( nCharged );
  // End of event loop. Statistics. Histogram. Done.
  }
  pythia.statistics();
  cout << mult;
  return 0;
}
```

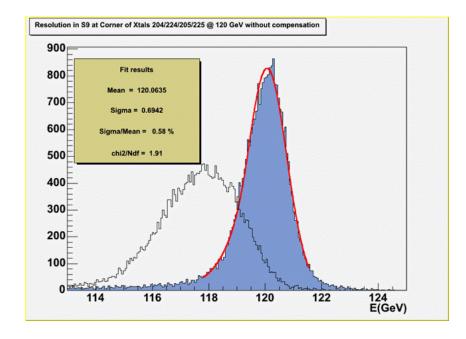

Detector effects

- Accelerators strive to emulate nature
- Monte Carlo strives to reproduce accelerator collision events
- But our detectors are never perfect!
- Every detector can be simulated by software
 - Making use of knowledge of particle interactions with matter
 - Needs precise knowledge of detector geometry, magnetic field, gas status etc
 - Although largely deterministic, has some probabilistic effects as well

- Most complete detector simulation software: GEANT (version 4 is the latest)
 - Pythia (or other good Monte Carlo) and GEANT are absolutely necessary to calculate corrections for detector inefficiencies

Final analysis: ROOT

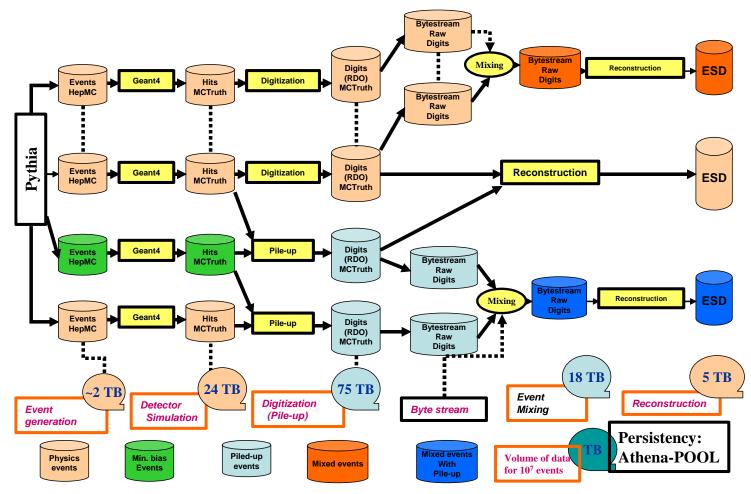

ROOT is a C++ based tool and framework (program and library) for data analysis

- C++ as script language with interpreter
- GUI for interactive visualization
- I/O and analysis of large amount of data
- Histograming, plotting, fitting
- Physics and mathematics
- Object organisation
- Parallel analysis via network

Final analysis: ROOT

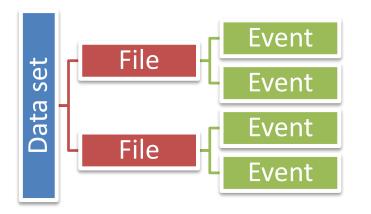

- ✤ As a tool
 - Makes use of commands to display and manipulate data
 - Commands are in C++
 - (covers ~85% of the full language including simple templates)
 - Can be used to prototype new code
- ✤ As a framework
 - Can be used as a library and be linked from user C++ code (LGPL license)
 - The result can be used by the tool
- Supports user classes
 - User can define new classes
 - Can do this either as a tool or as a framework
 - These can inherit from native ROOT classes

Monte Carlo data production flow (10 Mevents)

Very different tasks/algorithms (ATLAS experiment in this example)
Single "job" lasts from 10 minutes to 1 day
Most tasks require large amounts of input and produce large output data

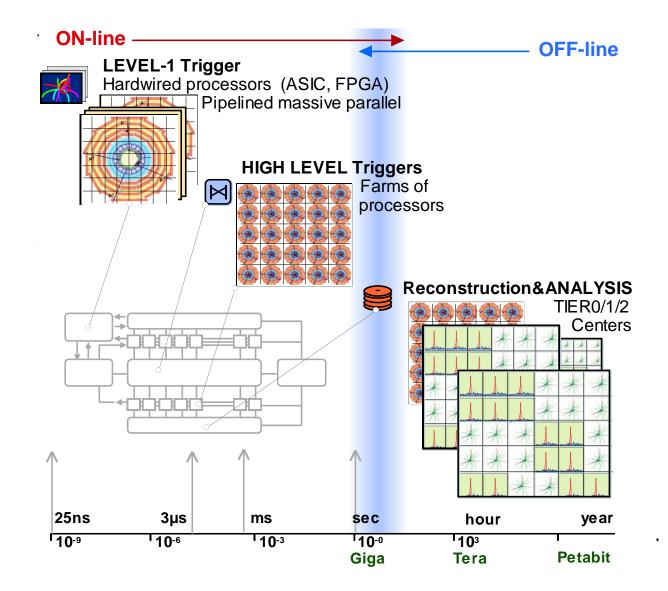

HEP data hierarchies

- Different experiments use different data models
- Since collision events are independent, they can be collected into files almost arbitrarily
 - Typically, a data set corresponds to a specific physics or simulation episode ("run")
- Data sets are derived from each other: from raw data to analysis objects

Physics selection at LHC - CMS experiment example

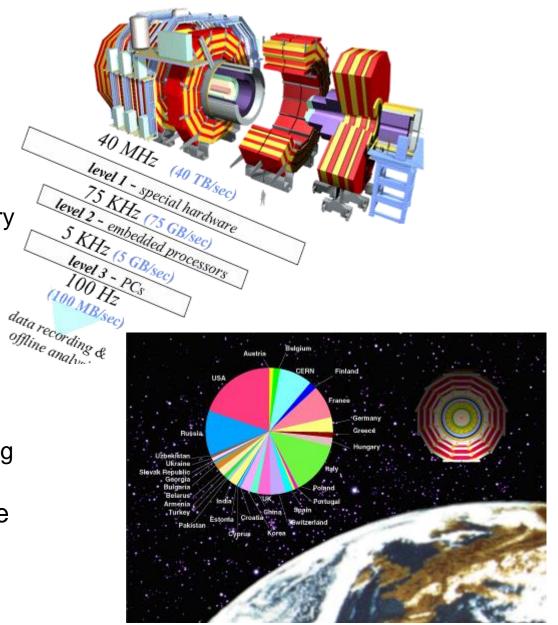

Data analysis frameworks

- ✤ HEP experiments are fiercely protective of their data
- Raw data are stored in proprietary formats and are not available for people outside experiments
 - This restriction is normally lifted after experiment stops operating
 - LHC experiments start making some data available publicly
- Every experiment develops own set of analysis software
 - Facilitates detector-specific activities (Monte Carlo, GEANT, reconstruction, calibration etc)
 - Implements computing model
 - Handles remote access to date
 - etc
- Typically, all HEP software frameworks have command line interfaces and are developed for Linux
 - HEP community even developed an own Linux flavour: Scientific Linux (RedHat derivative)

HEP computing specifics

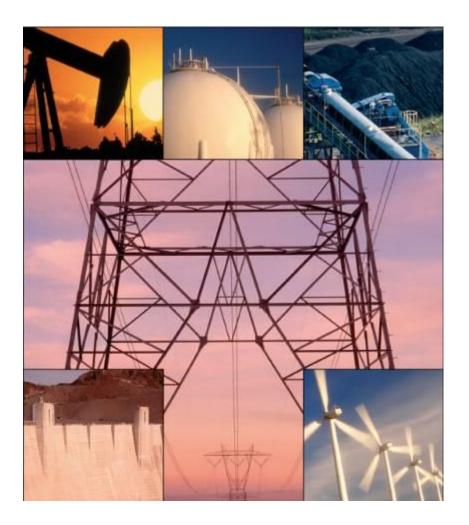

- Data-intensive tasks
 - Large datasets, large files
 - Lengthy processing times
 - Large memory consumption
 - High throughput is necessary
- Very distributed resources
 - Distributed computing resources of <u>modest</u> size
 - Produced and processed data are also distributed
 - Issues of coordination, synchronization and authorization are outstanding
- HEP is not unique in its demands, but we are first, we are many, and we *have* to solve it

Software for HEP experiments

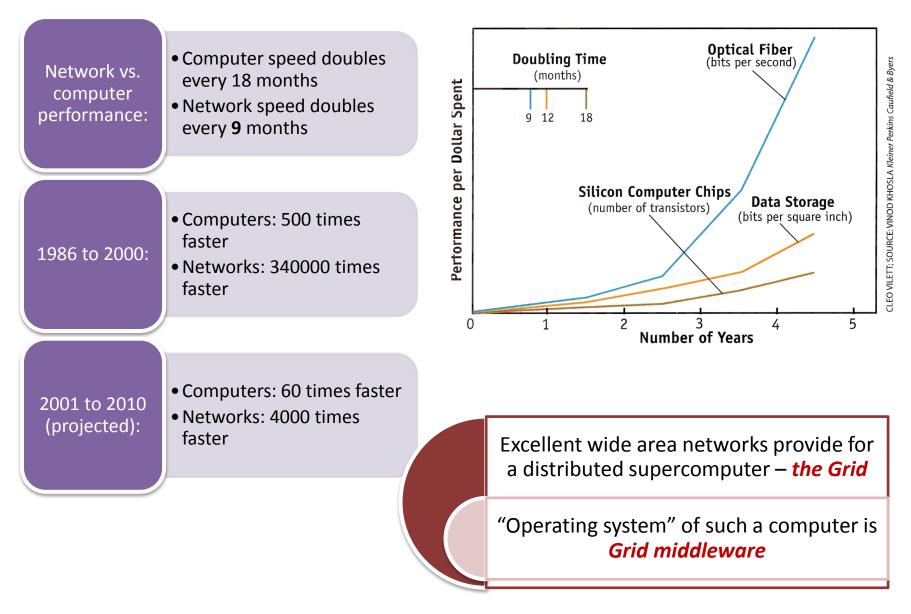

Massive pieces of software	 Written by very many different authors in different languages (C++, Python, FORTRAN etc) Dozens of external components
Frequent releases	 Occupy as much as ~10 GB of disk space each release Releases can come as often as once a month
Difficult to set up outside the lab	 Software is often tuned to the specifics of one lab (e.g. Scientific Linux operating system)
Unfeasible to be maintained locally by small university teams	 Plan A: do everything centrally at the lab Plan B: use <u>Grid</u> to connect large external computing "plants" managed by teams of experts

Origin of the word "Grid"

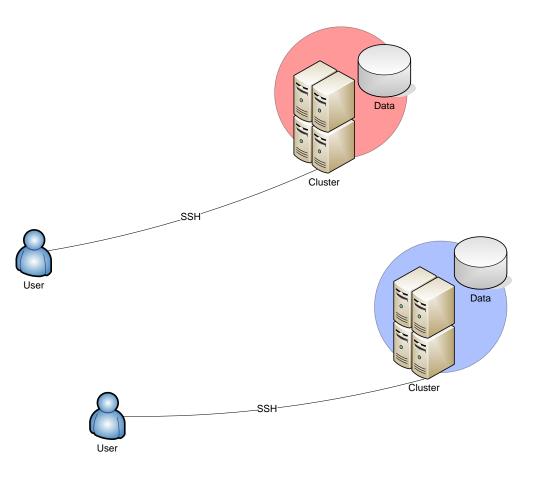

- Coined by lan Foster and Carl Kesselman around 1997
- Refers to computing grids as analogy of power grids
 - Many producers
 - Competing providers
 - Simple for end-users
- Spelled "grid" or "Grid"

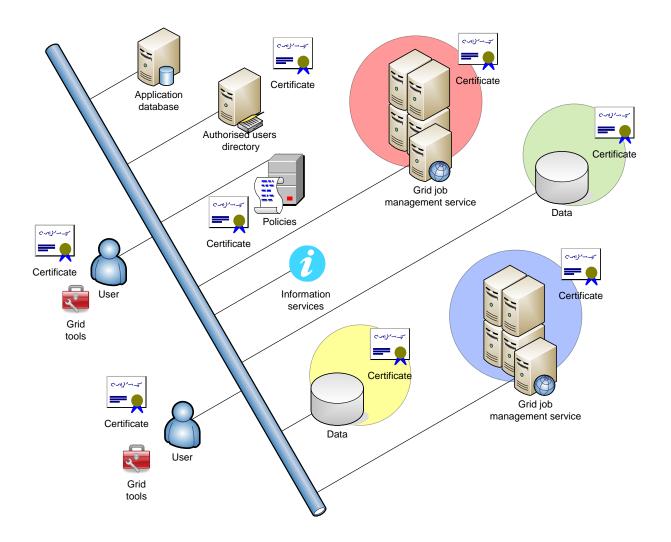

Grid is a result of IT progress

From the conventional computing...

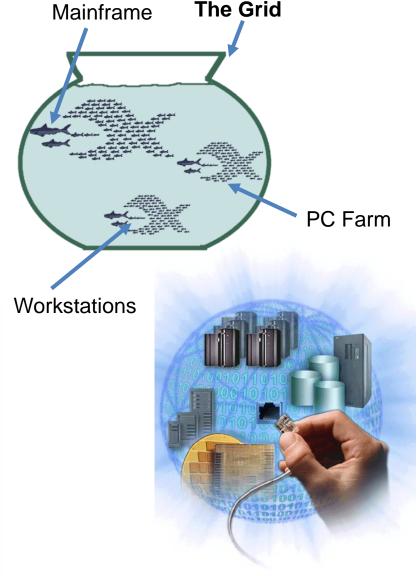

To the Grid

The Grid Paradigm

- Distributed "supercomputer" making use of fast networks
- Access to the great variety of resources by a single pass – a digital certificate
- Distributed data management
- A new scientific tool

Lund University

Grid usage in LHC experiments

- Almost all Monte Carlo and data processing today is done via Grid
- There are many Grid flavors and systems out there
 - Almost all are tailored for a specific application and/or specific hardware
- LHC experiments make use of only 3 Grid flavors:
 - gLite
 - ARC

– OSG

- All experiments develop own higher-level Grid middleware layers
 - ALICE AliEn
 - ATLAS PANDA, Rucio etc
 - LHCb DIRAC, GANGA
 - CMS ProdAgent, CRAB, PhEDEx etc

What is an LHC "Tier1" center

GB

1 TB

- WLCG: Worldwide LHC Computing Grid
 - A CERN project aiming to provide HEP computing infrastructure
 - Tiered structure: Tier0 at CERN, a dozen of regional Tier1s, local Tier2s
- WLCG Tier1 is:
 - Storage for replicated data (tapes and disks)
 - Data indexing service
 - Computing power
 - 24/7 on-call support system
 - Infrastructure: network, power, cooling, safety etc

2 HC

- File transfer services between Tiers
- Experiment-specific interfaces ("VOBoxes")
- Database services
- etc

RAL

Lund University

SARA

NOM2

Ilustration: Sandbox Studic

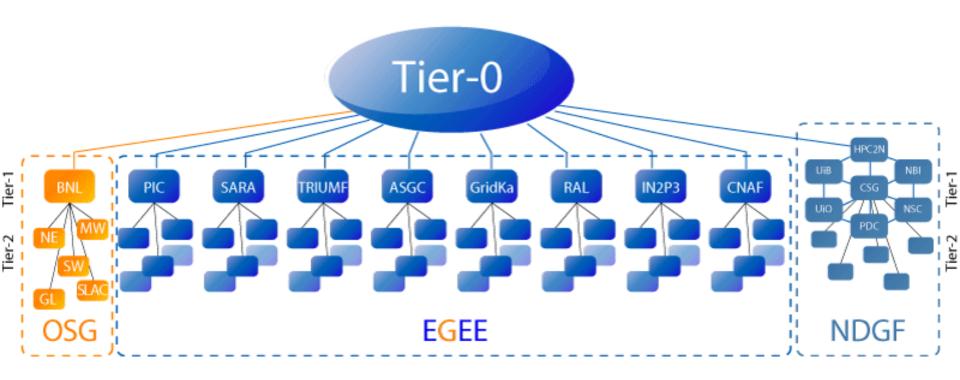

CERN

CNAF

ATLAS Multi-Grid Infrastructure

Graphics from a slide by A. Vaniachine

Where do I start on my way to Grid?

- Ask local sysadmin to install a Grid client
 - ARC client is the easiest: you can even install it yourself
- Apply for a "passport": the Grid certificate
 - Use your LU login at TERENA eScience Portal
 - Procedures are different in different countries
- Apply for a "visa": become an appropriate Virtual Organization (VO) member
 - e.g. ATLAS VO
- Ask a knowledgeable person which Grid system is used by your collaboration/group
 - Read the manual (if exists) or ask someone who used Grid before to help

What future holds

So far, Grid concept works well for HEP

- All LHC data today are processed on the Grid
- All Monte Carlo for LHC is run on the Grid
- Most data analysis is also on the Grid
- Still, there are many Grid flavors around
 - Some are tailored for HEP, some are not
- One common Grid for all sciences still did not emerge
 - Different sciences use very different approaches
- Possible alternative: Cloud computing
 - Grid is about federating different, even small, resources on a long term basis – good for scientists
 - Cloud is about renting out huge resources for a short time good for business (Amazon, Google, Microsoft)
 - HEP will probably stay with Grid for a foreseen while
