

Experimental Astroparticle Physics (a short introduction)

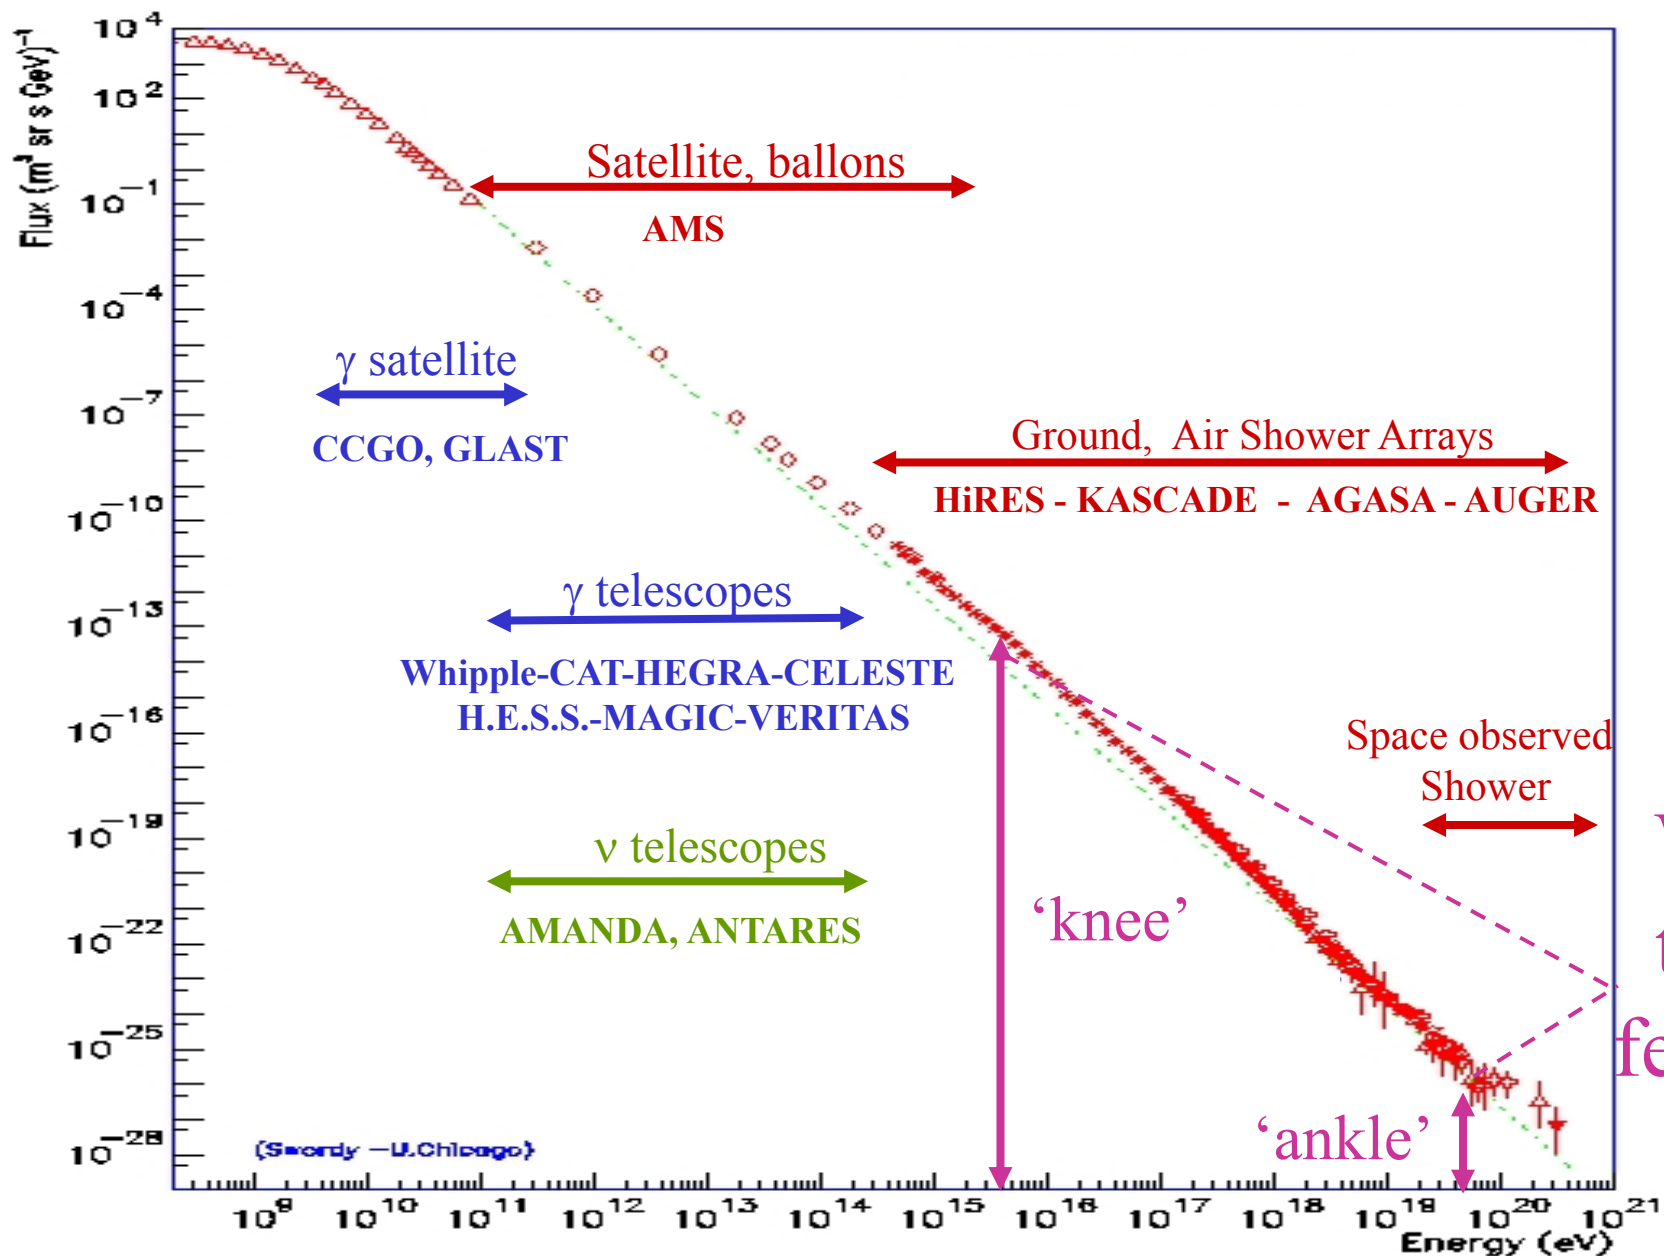

Alessandro De Angelis
INFN & Univ. Udine; IST Lisboa

Lund 2009

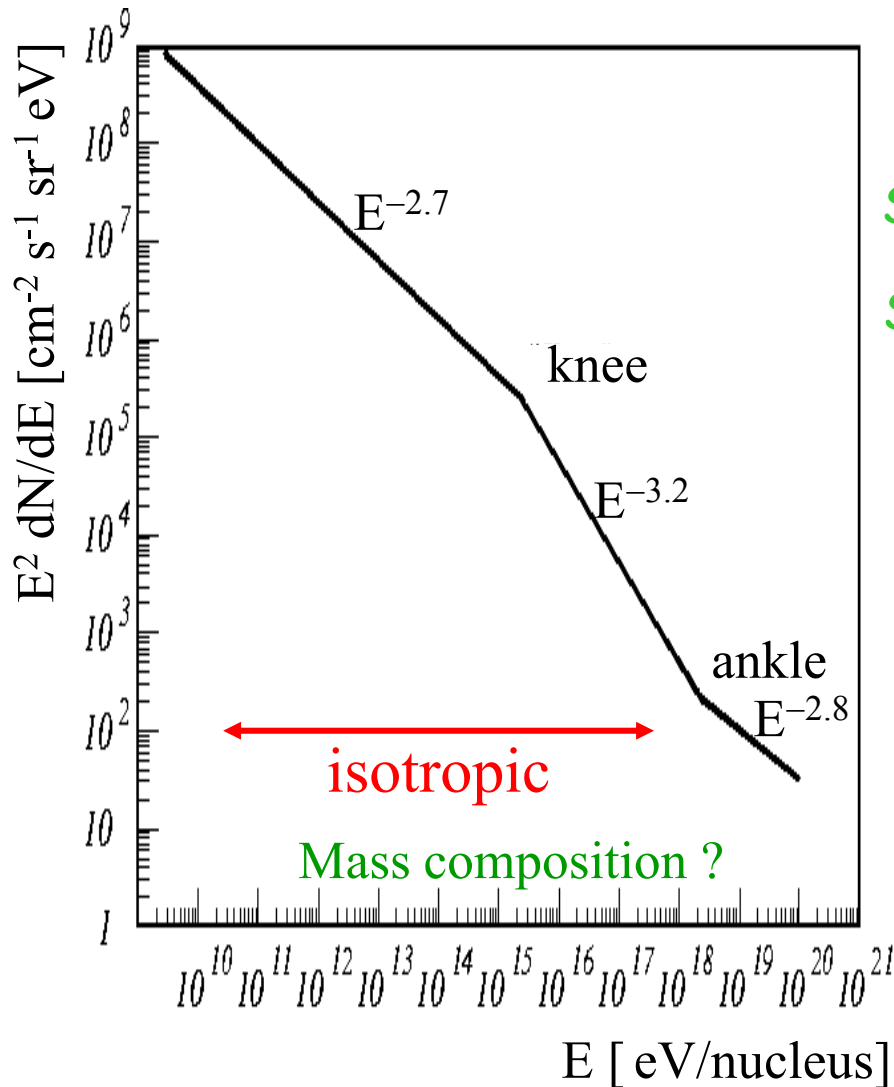

Lectures 3-4

Charged Cosmic Ray Energy Spectrum

Why these features ?

Features of Cosmic Ray Spectrum

Ingredients of models:

$$\frac{dN}{dE} \sim E^{\alpha + \delta}$$

Source acceleration: $\alpha = -2.0$ to $-2.2, \dots$

Source cut-off $E < 10^{18} Z \left[\frac{R}{\text{kpc}} \right] \left[\frac{B}{\mu\text{G}} \right] \text{eV}$

Diffusion models $\delta = -0.3$ to -0.6

GZK cut-off on CMB $\gamma E \approx 7 \cdot 10^{19} \text{eV}$

‘Conventional Wisdom’:

Galactic SNR $E < 3 \cdot 10^{18} \text{eV}$

Extragalactic $E > 3 \cdot 10^{18} \text{eV}$

exotic $E > 7 \cdot 10^{19} \text{eV}$

How are they produced?

(Possible acceleration sites)

- Wherever you have gravitational collapses, you can convert gravitational potential energy into kinetic energy of particles
 - Galactic sources (supernova remnants, binaries...) certainly able to produce particles up to ~ 100 TeV
 - Below the knee?
 - Galactic magnetic field $\sim 1-3$ μG can trap protons up to the knee
 - Beyond this energy? Active Galactic Nuclei (supermassive black holes, $\sim 10^9$ solar masses, accreting at the expense of local matter – with big flares)

Mass composition at knee

Average shower depth and ratio N_μ / N_e sensitive to primary mass
 (NB. Mass composition extracted is very sensitive to Monte Carlo simulation)

KASCADE \Rightarrow series of knees at different energies: p, He, ..., C, ..., Fe.
 $E(\text{Knee}) \propto Z \Rightarrow$ knee due to source confinement cut-off?

'GZK cutoff'

Interaction with background γ
(infrared and 2.7K CMBR)

HE cosmic rays

HE gamma rays

Are we observing new fundamental physics?

Explanations of Ankle/ $E > 10^{20}$ eV events

Astronomy type explanations

- ‘Bottom-Up’ : acceleration
 - pulsars in galaxy,
 - radio lobes of AGN (proximity a problem due to GZK, also should see source)

Particle Physics type explanations

- ‘Top-Down’ : decay of massive particles
 - GUT X particles with mass $> 10^{20}$ eV and long lifetimes
 - Topological defects
- **New Physics (Lorentz violation)**
- **They don’t exist...**
(favorite explanation after Auger results)

HiRES (Fly's Eye)

AUGER

2 sites each 3000km², $E > 5.10^{18}eV$

Southern site,
Mendoza Province,
Argentina

Water Cherenkov
Tanks
(1600 each 10m²)

Fluorescence Telescopes (6 telescopes each 30° × 30° at 4 sites)

The origin of cosmic rays at VHE

- On Nov 9, 2007, the Pierre Auger Collaboration (J. Cronin, A. Watson et al.) published in Science an article saying that
 - Out of 15 events with energies $>$ than about 60 EeV, 12 were located within 3.1° of AGN closer than 75 Mpc from Earth

Conclusion from the Auger result

- Active Galactic Nuclei are the main source of VHE cosmic rays
- First measurement of the extragalactic magnetic field:

$$B \sim 0.1 - 1 \text{ nG}$$

(dA, Roncadelli and Persic 2007, arXiv:0711.3346)

A new concept: EUSO (and ...)

- The **Earth atmosphere** is the ideal detector for the Extreme Energy Cosmic Rays and the companion Cosmic Neutrinos. The new idea of EUSO (2012?-) is to watch the fluorescence produced by them from the top

IV

Detectors for multimessenger astrophysics

We see only partly what surrounds us

- We see only a narrow band of colors, from red to purple in the rainbow
- Also the colors we don't see have names familiar to us: we listen to the radio, we heat food in the microwave, we take pictures of our bones through X-rays...

What about the rest ?

- What could happen if we would see only, say, green color?

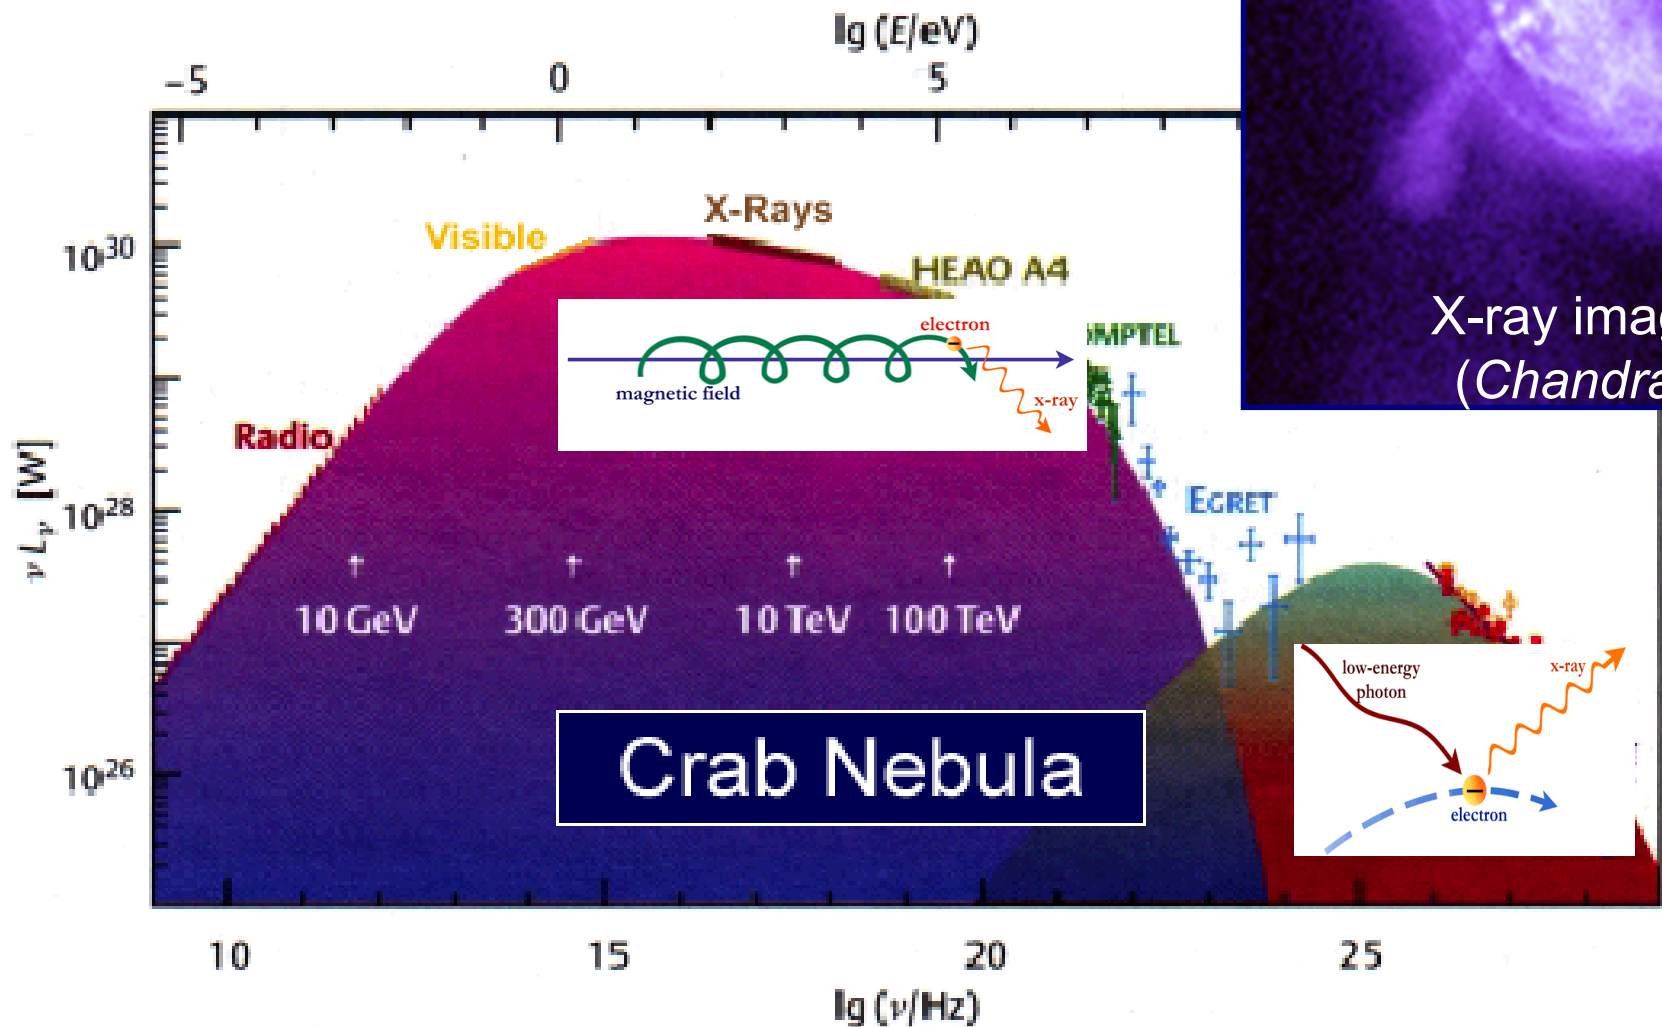

The universe we don't see

- When we take a picture we capture light (a telescope image comes as well from visible light)
- In the same way we can map into false colors the image from a “X-ray telescope”
- Elaborating the information is crucial

Many sources radiate over a wide range of wavelengths

Pulsars

- Rapidly rotating neutron stars with
 - T between $\sim 1\text{ms}$ and $\sim 1\text{s}$
 - Strong magnetic fields ($\sim 100\text{ MT}$)
 - Mass ~ 3 solar masses
 - R $\sim 10\text{ Km}$ (densest stable object known)
- For the pulsars emitting TeV gammas, such an emission is unpulsed

Multi Messenger Astronomy

Radio Telescope
(Bonn)

Optical Telescope

X - ray Satellite
(INTEGRAL/ESA)

γ - ray Telescope

View of sky in Galactic Coordinates in four different photon wavelengths

Radio

Visible light

X - rays

γ rays

Centre of Galaxy in Different Photon Wavelengths

Radio 408 Mhz

Infrared 1-3 μm

Visible Light

Gamma Rays

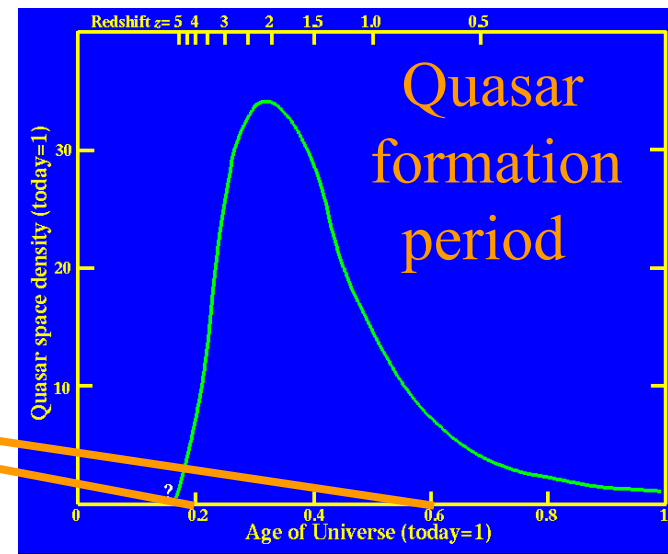

Multi-Messengers to see Whole Universe

Distant universe invisible in high energy photons

need neutrinos

But also...

- Neutrino astrophysics
- *Graviton (?) astrophysics*

Surprises in history of astrophysics

New instruments often give unexpected results:

Telescope	User	date	Intended Use	Actual use
Optical	Galileo	1608	Navigation	Moons of Jupiter
Optical	Hubble	1929	Nebulae	Expanding Universe
Radio	Jansky	1932	Noise	Radio galaxies
Micro-wave	Penzias, Wilson	1965	Radio-galaxies, noise	3K cosmic background
X-ray	Giacconi ...	1965	Sun, moon	neutron stars accreting binaires
Radio	Hewish, Bell	1967	Ionosphere	Pulsars
γ -rays	military	1960?	Thermonuclear explosions	Gamma ray bursts

With future new detector can again hope for completely new discoveries

The high-energy γ spectrum

$$E_\gamma > 30 \text{ keV} (\lambda \sim 0.4 \text{ \AA}, \nu \sim 7 \cdot 10^9 \text{ GHz})$$

Although arbitrary, this limit reflects astrophysical and experimental facts:

- Thermal emission \rightarrow nonthermal emission
- Problems to concentrate photons (\rightarrow telescopes radically different from larger wavelengths)
- Large background from cosmic particles

Transparency of the atmosphere

Detection of a high E photon

- Above the UV and below “50 GeV”, shielding from the atmosphere
 - Below the e^+e^- threshold + some phase space (“10 MeV”), Compton/scintillation
 - Above “10 MeV”, pair production
- Above “50 GeV”, atmospheric showers
 - Pair \leftrightarrow Brem

Consequences on the techniques

- The earth atmosphere ($28 X_0$ at sea level) is opaque to X/γ Thus **only a satellite-based detector can detect primary X/γ**

- The fluxes of h.e. γ are low and decrease rapidly with energy
 - Vela, the strongest γ source in the sky, has a flux above 100 MeV of $1.3 \cdot 10^{-5}$ photons/(cm^2s), falling with $E^{-1.89} \Rightarrow$ a 1m^2 detector would detect only 1 photon/2h above 10 GeV \Rightarrow **with the present space technology, VHE and UHE gammas can be detected only from atmospheric showers**
 - Earth-based detectors, atmospheric shower satellites
- The flux from high energy cosmic rays is much larger

Satellite-based and atmospheric: complementary, w/ moving boundaries

Satellite-based detectors: figures of merit

- Effective area, or equivalent area for the detection of γ

$$A_{\text{eff}}(E) = A \times \text{eff.}$$

- Angular resolution is important for identifying the γ sources and for reducing the diffuse background
- Energy resolution
- Time resolution

X detectors

- The electrons ejected or created by the incident gamma rays lose energy mainly in ionizing the surrounding atoms; secondary electrons may in turn ionize the material, producing an amplification effect
- Most space X- ray telescopes consist of detection materials which take advantage of ionization process but the way to measure the total ionization loss differ with the nature of the material

Commonly used detection devices are...

- gas detectors
- scintillation counters
- semiconductor detectors

X detection (direction-sensitive)

A **coded mask** (array of opaque blocks) is disposed so that a point source at infinity projects on a position sensitive detector a **pattern characteristic of the source direction**

Coded mask

Position sensitive
detector

X detection (direction-sensitive)

Unfolding is a nice mathematical problem !₃₃

INTEGRAL/CHANDRA

- INTEGRAL, the International Gamma-Ray Astrophysics Laboratory is an ESA medium-size (M2) science mission
- Energy range 15 keV to 10 MeV plus simultaneous X-ray (3-35 keV) and optical (550 nm) monitoring
- Fine spectroscopy ($\Delta E/E \sim 1\%$) and fine imaging (angular resolution of 5')
- Two main -ray instruments: SPI (spectroscopy) and IBIS (imager)
- Chandra, from NASA, has a similar performance

γ satellite-based detectors: engineering

- Techniques taken from particle physics

- γ direction is mostly determined by e^+e^- conversion

- Veto against charged particles by an ACD
- Angular resolution given by
 - Opening angle of the pair $m/E \ln(E/m)$
 - Multiple scattering $(20/p\beta) (L/X_0)^{1/2}$ (dominant)

=> large number of thin converters, but the # of channel increases
(power consumption \ll 1 kW)

- If possible, a calorimeter in the bottom to get E resolution, but watch the weight (leakage => deteriorated resolution)

Smart techniques to measure E w/o calorimeters (AGILE)

GLAST/Fermi

- γ telescope on satellite for the range 20 MeV-300 GeV
 - hybrid tracker + calorimeter
- International collaboration US-France-Italy-Japan-Sweden
 - Broad experience in high-energy astrophysics and particle physics (science + instrumentation)
- Timescale: 2008-2013 (->2018)
- Wide range of physics objectives:
 - Gamma astrophysics
 - Fundamental physics

Fermi: the instrument

- Tracker
Si strips + converter
 - Calorimeter
CsI with diode readout
- (a classic for HEP)
- $1.7 \times 1.7 \text{ m}^2 \times 0.8 \text{ m}$
height/width = 0.4 \Rightarrow
large field of view
 - 16 towers \Rightarrow modularity

GLAST: the tracker

Si strips + converter

- High signal/noise
- Rad-hard
- Low power
- 4x4 towers, of 37 cm \times 37 cm of Si
- 18 x,y planes per tower
 - 19 “tray” structures
 - 12 with 2.5% Pb on bottom
 - 4 with 25% Pb on bottom
 - 2 with no converter
- Electronics on the sides of trays
 - Minimize gap between towers
- Carbon-fiber walls to provide stiffness

GLAST performance (compared to EGRET)

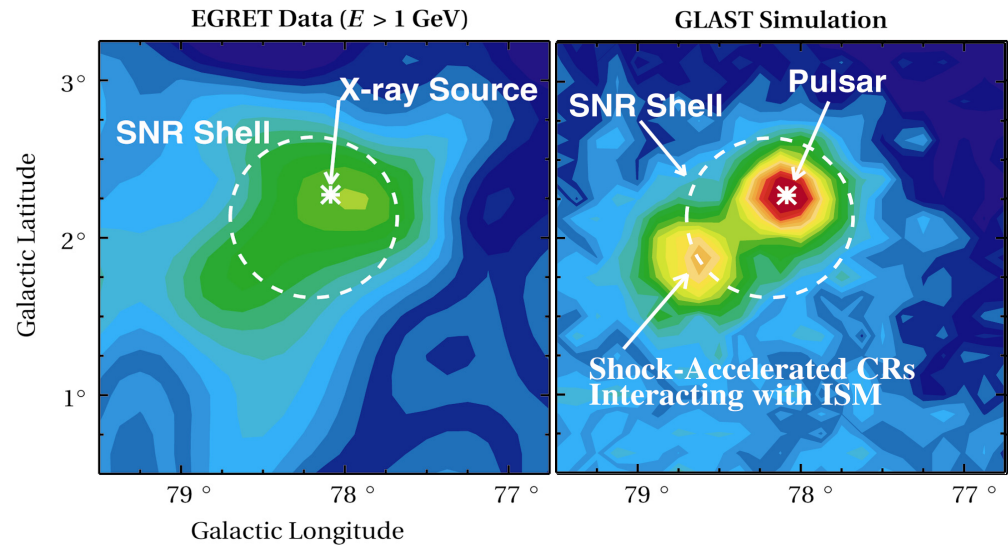

Quantity	GLAST	EGRET
Energy range	20 MeV- > 300 GeV	20 MeV- 30 GeV
Energy resolution	10 % (E>100 MeV)	10%
Peak Effective Area	> 8000 cm ² (E>1 GeV)	1500 cm ²
Single photon angular resolution (68%, on-axis)	<3.5 deg (100 MeV) <0.15 deg (E>10 GeV)	5.8 deg (100 MeV)
*Field of view (FOV)	> 2 sr	0.5 sr
Time resolution	10 microseconds	0.1 milliseconds
Dead time	< 20 microsec/event	100 ms/event

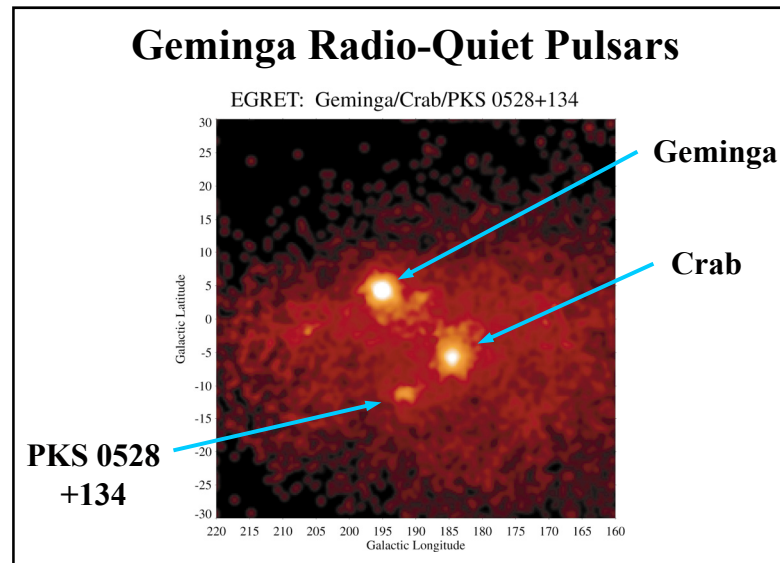

GLAST performance

two examples of application

- Cosmic ray production

- Facilitate searches for pulsations from millisecond pulsars

The Gamma-ray Large Area Space Telescope

GLAST sent to space in June 2008

A collaboration USA-Japan-France-Italy-Sweden

Large part of the software is written in Udine... So come and help !

The Universe in the gamma rays after one year of data taking. Center: our galaxy

But despite the progress in satellites...

- The problem of the flux (~ 1 photon/day/km² @ ~ 30 PeV) cannot be overcome
 - Photon concentrators work only at low energy
 - The key for VHE gamma astrophysics and above is in ground-based detectors
 - Also for dark matter detection...

Earth-based detectors

Properties of Extensive Air Showers

- We **believe** we know well the γ physics up to EHE...

Predominant interactions e.m.

- e⁺e⁻ pair production dominates
- electrons loose energy via brem
- Rossi approximation B is valid
 - Maximum at $z/X_0 \approx \ln(E/\epsilon_0)$; ϵ_0 is the critical energy ~ 80 MeV in air; $X_0 \sim 300$ m at stp
 - Cascades \sim a few km thick
 - Lateral width dominated by Compton scattering \sim Moliere radius (~ 80 m for air at STP)

- Note: $\lambda_{\text{had}} \sim 400$ m for air

hadronic showers have 20x more muons and are less regular than em

Ground detectors: EAS vs. IACT

- EAS (Extensive Air Shower): detection of the charged particles in the shower
- Čerenkov detectors: (IACT): detection of the Čerenkov light from charged particles in the atmospheric showers

EAS

MILAGRO (New Mexico @ 2600m)
water Cherenkov,
60x80m² + outriggers,
 γ/h : Muon-identification
in second layer)

Proposed: HAWC

TIBET-AS (@4300M A.S.L.)
SCINTILLATOR-ARRAY, 350x350M²
SEE: CRAB, MKN421

SOON:
ARGO-YBJ
6500M² RPC

Cherenkov (Č) detectors

Cherenkov light from γ showers

- Č light is produced by particles faster than light in air
- Limiting angle $\cos \theta_c \sim 1/n$
 - $\theta_c \sim 1^\circ$ at sea level, 1.3° at 8 km asl
 - Threshold @ sea level : 21 MeV for e, 44 GeV for μ

Maximum of a 1 TeV γ shower ~ 8 Km asl

200 photons/m² in the visible

Duration ~ 2 ns

Angular spread $\sim 0.5^\circ$

Observational Technique

- Image intensity \rightarrow Shower energy
- Image orientation \rightarrow Shower direction
- Image shape \rightarrow Primary particle

Systems of Cherenkov telescopes

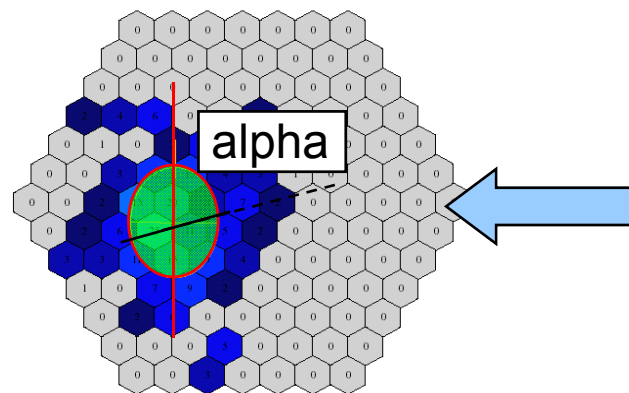

Gamma / hadron separation

Gamma shower
(narrow, points to source)

Proton shower
(wide, points anywhere)

IACT vs Satellite

- Satellite :

- primary detection
- small effective area $\sim 1\text{m}^2$
 - lower sensitivity
- large angular opening
 - search
- large duty-cycle
- large cost
- lower energy
- low bkg

- IACT/ground based

- secondary detection
- huge effective area $\sim 10^4\text{m}^2$
 - Higher sensitivity
- small angular opening
 - Serendipity search
- small duty-cycle
- low cost
- high energy
- high bkg

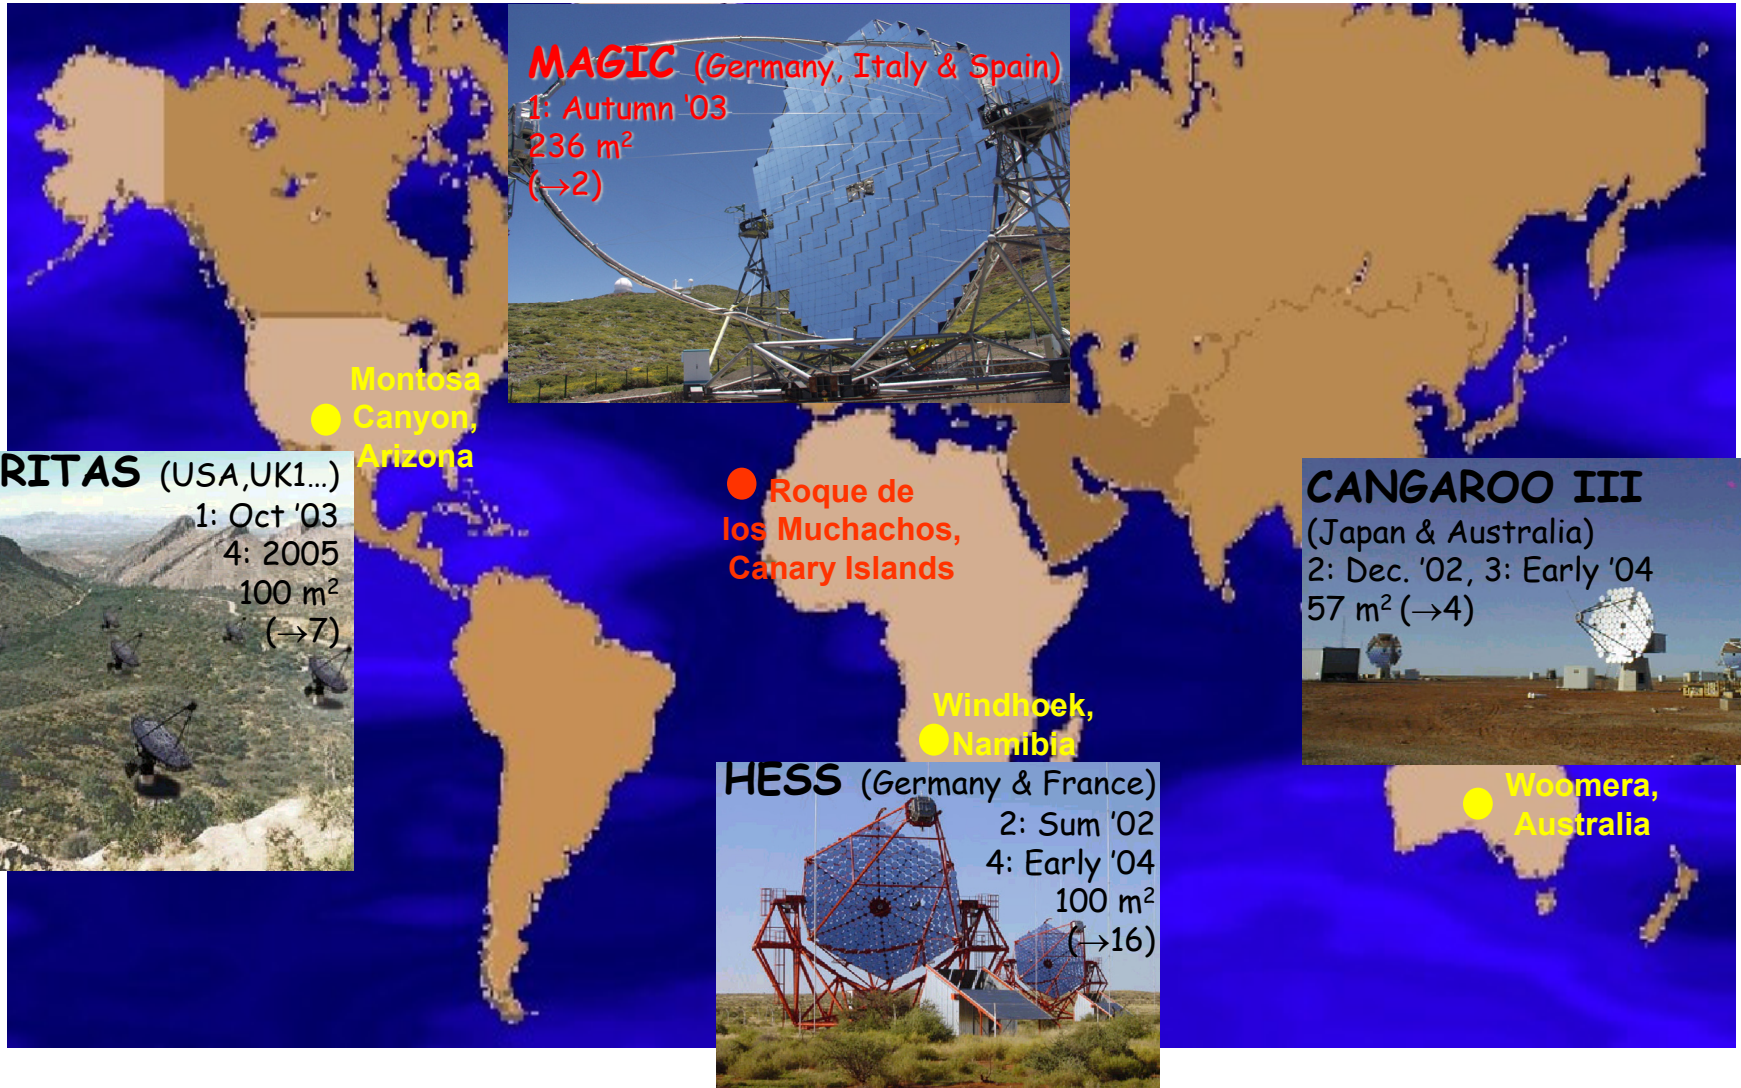

Ground-based detectors

Improvements in atmospheric Č

- Improving flux sensitivity
 - Detect weaker sources, study larger sky regions $S/B^{1/2}$
 $\propto (A/\tau\Omega)^{1/2}$
 - Smaller integration time
 - Improve photon collection, improve quantum efficiency of PMs
 - Use several telescopes
- Lowering the energy threshold
 - Close the gap ~ 100 GeV between satellite-based & ground-based instruments

The “Big Four”

DETECTOR PARAMETERS

In 2009:	#	~mirror area m ²	Camera pixels	FOV deg	Altit. m asl	arrangement
CANGAROO	4x	57	427	4	160	 ~100m
H.E.S.S.	4x	107	960	5	1800	 ~120m

IACT Scientific Highlights

Galactic observations:

- I. Discovery of many new Galactic sources by HESS:**
 - *HESS GP Survey & targeted observations.*
- II. Detailed studies of Galactic sources by HESS:**
 - *Precision measurements (spectra, morphology, etc.).*
 - *Theoretical models and understanding.*
- III. Discovery of new classes of VHE gamma-ray emitters by HESS:**
 - *First variable galactic source*
- IV. Study of the Galactic Center by CANGAROO, HESS and MAGIC:**
 - *Evidence for a TeV signal; search for DM annihilation*
- V. New class of periodical galactic sources by MAGIC and HESS**

Scientific Highlights

Extragalactic observations:

VII. Discovery of ~30 new AGN by HESS and MAGIC:

- *Measurements of AGN properties and multi- λ studies.*
- *Constraints on cosmological EBL density from absorption spectrum.*

VI. Observation of AGN with orphan flares by MAGIC:

- *Connexion to neutrino and UHECR astronomy?*

VIII. High time-resolution study of AGN flares by MAGIC:

- *New constraints on emission mechanisms and light speed dispersion relations.*

IX. Prompt follow-up of 11 GRB (implosion of hypernovae) by MAGIC:

- *GRB follow-up in coincidence with observation in the X-ray domain.*

Violation of the Lorentz-Invariance?

Light dispersion due to quantum gravity effects expected in some QG models

$$V = c [1 \pm \xi (E/E_{QG}) - \xi_2 (E/E_{QG})^2 \pm \dots]$$

1st order $\Delta t \sim \xi \frac{E}{E_{QG}} \frac{z}{H_0} = \xi \frac{E}{E_{QG}} \frac{L}{c}$

MAGIC Mkn 501, arXiv:0708.2889

$$E_{QG} \sim 0.03 M_p$$

$$E_{QG} > 0.02 M_p$$

HESS PKS 2155, ICRC 2007 prel.

$$E_{QG} > 0.04 M_p$$

Whipple 1999, PRL 83(1999)2108

$$E_{QG} > 0.005 M_p$$

GRB X-ray limits:

$$E_{QG} > 0.001 \dots 0.01 M_p$$

... but in most scenarios

$$\Delta t \sim (E/E_{QG})^\alpha, \alpha > 1$$

▶ VHE gamma rays even better

▶ Mrk 501: $E_{QG} > 3 \cdot 10^{-9} M_p$, $\alpha=2$

Mrk 501,
MAGIC, astro-ph/0702008

Propagation physics

Selection bias?
New physics ?

(Persic & AdA, arXiv:0711.2317)

Absorption:

visible/infrared light
accumulated by all
stars in history of Universe

Too large transparency of the Universe to gamma rays

- More than 20 AGN at VHE discovered by γ telescopes
 - Including 3C279 at $z=0.54$
- Unexpectedly large, due to attenuation expected for γ
 - Dominant process for the absorption of γ is

$$\sigma(E, \epsilon) = 1.25 \cdot 10^{-25} (1 - \beta^2) \left[2\beta(\beta^2 - 2) + (3 - \beta^4) \ln \left(\frac{1 + \beta}{1 - \beta} \right) \right] \text{cm}^2$$

maximal for

$$\epsilon \simeq \frac{2m_e^2 c^4}{E} \simeq \left(\frac{500 \text{ GeV}}{E} \right) \text{eV}$$

- Only QED, relativity and cosmology in the formula above
 - For γ rays, relevant background component is optical/infrared (EBL)
 - EBL density given by cosmology/star formation
- How to explain observations?

Interaction with a new light neutral boson?

(AdA, Roncadelli & Mansutti [DARMA],
arXiv:0707.4312)

- Photons might oscillate into a neutral (pseudo)scalar particle ϕ of mass m , which travels unimpeded
- ϕ interacting with γ through the Lagrangian

$$L = -\frac{1}{4M} \varepsilon^{\mu\nu\rho\sigma} F_{\mu\nu} F_{\rho\sigma} \phi = \frac{1}{M} (\vec{E} \cdot \vec{B}) \phi$$

- If $m(\phi) \ll 10^{-10}$ eV (1 μ K) and $M > 3 \cdot 10^{11}$ GeV the experimental observations are explained!
