

### Modern Experimental Particle Physics FYST17 *February 12 and 15, 2018*

## An introduction to the Quark Gluon Plasma and heavy-ion collisions P. Christiansen (Lund University)

## Outline

- The medium temperature
- Hard probes
  - The standard candles
  - Quarkonium
  - Jets and high  $p_{\rm T}$  particles
- Soft medium properties
  - Collective flow
- Quark Gluon Plasma (QGP) in small systems?

# Let us recall what is special about QCD

FYST17

### QED vs QCD

#### QED: superposition principle

QCD: color fields interact (form flux tube at long distance)

### The strong interaction: Quantum Chromo Dynamics (QCD)

3 strong charges (red, green, blue) Particles in nature are color neutral Quarks are "confined"

FYST17

### Deconfinement at high energy densities

FYST17

At high energy densities a new form of matter exists: Quark-Gluon Plasma, where quarks&gluons are deconfined We will only talk about the high temperature transition which is what we probe in heavy-ion collisions

Tc ~ 160 MeV (2.000.000.000.000 K)

### What is the Quark Gluon Plasma?

"`QGP' is not a new particle but a paradigm-shift of how we understand matter in extreme conditions. Thus there is no clear criterion by which one can claim an experimental discovery. For this reason QGP was rediscovered again with new experimental results obtained at the order of magnitude higher RHIC collision energies. In addition to confirming the CERN results, RHIC produced new puzzling phenomena; some will be discussed below. The circumstance repeats for the third time today: LHC data confirms SPS and RHIC results, and is offering another rich field of new experimental results.

Since no one plans to announce the QGP discovery at the LHC, we conclude that QGP has gained considerable acceptance as a new form of matter."

Johann Rafelski and Jeremey Birrell, arXiv:1311.0075.

They point out a big problem: our main understanding is experimental and very little of the theory is on a firm basis. When we will have a better theoretical picture we can then really point out what the QGP properties are and when it was discovered.

## Why do we study the QGP?

- New phase of matter predicted by QCD
  - Characterize its properties experimentally (and eventually be able to derive them)
- Cosmology: QGP phase transition in the early Universe (µs after Big Bang)
- New paradigm?
  - Circumvent traditional problem that while quarks and gluons are the fundamental degrees of freedom we observe hadrons to directly study the QCD dynamics of quarks and gluons

 $\varepsilon_{Quark-Gluon gas} =$ 

 $\frac{\pi^2}{30}$  (bosonic dof +  $\frac{7}{8}$  fermionic dof)  $T^4$ 

### Lattice QCD calculation of the energy density

With lattice QCD one can study some aspects of QCD numerically. In this case the energy density shows that at a temperature of ~170 MeV there is a phase transition. The phase transition is believed to be a Xover, meaning that for temperatures around Tc the hadronic and QGP phases coexist and that no entropy is produced in the phase transition.

With lattice QCD one can study some aspects of QCD numerically. In this case the energy density shows that at a temperature of ~170 MeV there is a phase transition. The phase transition is believed to be a Xover, meaning that for temperatures around Tc the hadronic and QGP phases coexist and that no entropy is produced in the phase transition.

### Heavy ion collisions

- The only way we can create the QGP in the laboratory!
- By colliding heavy ions it is possible to create a large (»1fm<sup>3</sup>) zone of hot and dense QCD matter
- Goal is to create and study the properties of the Quark Gluon Plasma
- Experimentally mainly the final state particles are observed, so the conclusions have to be inferred via models

#### QGP – the phase of the universe a few micro<sup>®</sup> seconds after The Big Bang

15

# History of ultra-relativistic heavy-ion physics

- 1<sup>st</sup> generation Vs<sub>NN</sub><20GeV (fixed target) AGS (BNL, US), SPS (CERN) late 80s and 90s
  - Experiments: NA61, NA49, NA60, NA50, NA44, .....
- 2<sup>nd</sup> generation Vs<sub>NN</sub><200GeV (collider) RHIC (BNL, US) 2000-Now
  - Experiments: PHENIX, STAR, PHOBOS, BRAHMS
- 3<sup>rd</sup> generation √s<sub>NN</sub>=2760GeV in run 1 (collider), √s<sub>NN</sub>=5020GeV in run 2 (2015-) LHC (CERN) 2010-Now
  - Experiments: ALICE, CMS, and ATLAS.

I will mainly show results from LHC!

## The ALICE experiment at LHC: Detecting the QGP

## The Time Projection Chamber: a 3D charged particle "camera"

17

FYST17

Lund is active on both the hardware and software side

## The Time Projection Chamber: a 3D charged particle "camera"

Lund is active on both the hardware and software side

# The three systems (understanding before 2012)

Hot QCD matter: This is where we expect the QGP to be created in central collisions.

QCD baseline: This is the baseline for "standard" QCD phenomena.

Cold QCD matter: This is to isolate nuclear effects, e.g. nuclear pdfs.

### **THERMAL PHOTONS**

21

# Measuring the medium temperature

- To establish the necessary conditions for a medium one would like to measure the temperature/energy density
- There are in general three possibilities
  - Extracting the final temperature from the  $p_{\rm T}$  slope and particle yields (this is the final temperature)
  - Bjorken has made a famous relation between the initial energy density and the final transverse energy (using hydrodynamics and assumptions on when a medium is formed) Phys. Rev. D27 (1983) 140-151 (2300 citations)
  - Measuring the thermal photon spectrum
    - Photons only interacts weakly with the QGP and so one can probe the early times directly (one measures the time integrated spectrum)

**FYST17** 22

## In a similar way as we measure the surface temperature of the sun...

(sin full)  $f_{isop}$  $f_{isop}$ 

... we can measure the temperature of the QGP

10

# Photon identification in the TPC via conversion

p\_ (GeV/c)

Construct double ratio to eliminate/reduce systematics

ALI-PREL-27936

- Numerator is the actual measurement ۲
  - **Denominator** is from a cocktail calculation

$$\gamma_{direct} = \gamma_{inc} - \gamma_{decay} = \left(1 - \frac{\gamma_{decay}}{\gamma_{inc}}\right) \cdot \gamma_{inc}$$

### Direct photons in pp collisions

Comparison to pQCD NLO calculation

### Direct photons in peripheral Pb-Pb collisions

• Peripheral Pb-Pb

Consistent with only direct and decay photons

### Direct photons in central Pb-Pb collisions

Central Pb-Pb

Surplus of photons at high pT is expected from hard production Surplus of photons at low pT are from thermal radiation from the QGP

### Direct photon spectrum in central Pb-Pb

- Obtain the direct  $\gamma$  spectrum by scaling with the inclusive  $\gamma$  spectrum

 The temperature of the low p<sub>T</sub> direct γ spectrum is of order 300 MeV (recall that this is a time average over the lifetime of the medium)

### The highest man-made temperature

Where

#### SWITZERLAND

When

#### 13 AUGUST 2012

On 13 August 2012 scientists at CERN's Large Hadron Collider, Geneva, Switzerland, announced that they had achieved temperatures of over 5 trillion K and perhaps as high as 5.5 trillion K. The team had been using the ALICE experiment to smash together lead ions at 99% of the speed of light to create a quark gluon plasma - an exotic state of matter believed to have filled the universe just after the Big Bang.

### HARD PROBES

### What happens when we collide pp and Pb-Pb?

32

FYST17

- Think for a few minutes
- Discuss with your neighbors for a few minutes

# What happens in pp and Pb-Pb collisions – a simple picture

# Hard probes in heavy-ion collisions

- The cross sections for Hard probes (HP) can in principle be calculated using pQCD (+ pdfs and FFs). In practice they need to be measured to achieve the best systematic precision.
- The cross sections can easily be extrapolated from pp to Pb-Pb collisions using binary scaling (next slide) unless there are "nuclear" effects
  - HP allow the precise study of nuclear effects
- Penetrating probes
- Strongly interacting probes
  - Heavy quarks (quarkonia), jets

35

FYST17

- The "medium" energy is proportional to the # of participant (Npart)
- The number of parton-parton (quark-quark, quark-gluon, gluongluon) is proportional to the # of binary collisions (Nbin)
- Example:

6 participant 8 binary collisions

(pp has 2 participant and 1 binary collision)

#### **Peripheral** Event

From real-time Level 3 display.

**STAR** 

#### **Mid-Central Event**

From real-time Level 3 display.

#### **Central Event**

From real-time Level 3 display.

# The nuclear modification factor R<sub>AA</sub> (1/2)

$$R_{AA} = \frac{d^2 N^{AA}/dp_T d\eta}{\langle T_{AA} \rangle d^2 \sigma^{pp}/dp_T d\eta}$$

 $< T_{AA} > \sigma^{pp} = < N_{coll} >$ N<sub>coll</sub> is the number of binary collisions

For perturbative QCD processes:  $R_{AA}$ <1: suppression  $R_{AA}$ =1: no nuclear effects  $R_{AA}$ >1: enhancement

Phys. Lett. B 696 (2011)

So  $R_{AA}$  is a way to quantify the nuclear effects!

39

## The nuclear modification

factor R<sub>AA</sub> (2/2)  $R_{AA} = \frac{d^2 N^{AA}/dp_T d\eta}{\langle T_{AA} \rangle d^2 \sigma^{pp}/dp_T d\eta}$ 

### Hard Probes: Standard candles

We need penetrating hard probes to validate the binary scaling

What could that be?

## Ncoll scaling for direct photons

- Direct photons does not interact with final state hadronic matter and the results confirm binary scaling of hard processes!
- The best standard candle at RHIC

#### **FYST17** 43

## New "standard candle" at LHC: ATLAS measures Z bosons

- The Z does not interact strongly and so can also be used to check binary scaling at LHC
  - Also the W have been used at LHC

#### HARD PROBES: HEAVY QUARKS

## Heavy quarks: I will only focus on Quarkonia

Lattice QCD results for the heavy quark potential (free energy): arXiv:0710.0498

Lattice QCD predicts that the long range force will be screened in the plasma Bound state properties will change and some states will disappear / melt Original idea:

"J/ψ Suppression by Quark-Gluon
Plasma Formation" by T. Matsui and
H. Satz
Phys.Lett. B178 (1986) 416
Cited by 2108 records

45

FYST17

#### LHC has delivered

CMS has proven to be a marvelous detector for bottomonium ALICE can complement by going to lower  $p_T$  for charmonium

These textbook results demonstrate the amazing capabilities of LHC detectors

### Suppression of heavy quarkonia can work as a thermometer

Note: 6.5<p\_<30 GeV for J/ $\psi$  and  $\psi$ (2s)

## Suppression qualitatively depends on binding energy as predicted

## J/ψ results from ALICE: Evidence for regeneration

The suppression of J/ $\psi$  at LHC is less than at RHIC! Understanding: due to the large cross section "random" charm and anti-charm quarks combine (see next slides)

## J/Psi differential results

The difference in suppression is visible at low  $\boldsymbol{p}_{T}$ 

## J/Psi differential results

The difference can be explained by J/ $\psi$  regeneration (much larger charm Xsection at LHC)

(This effect was already proposed before the RHIC results came out.)

# Caveat: cold nuclear matter effects are not understood

For J/ $\psi$  we have reasonable good description: energy loss really just means that due to collisions with other nucleons the rapidity of the J/ $\psi$  is shifted towards the Pb-nuclei. But why is the 2S state extremely suppressed in p-Pb (at the rapidity) where the 1S state is a bit enhanced?

## The relative production of Y states is affected by event activity (?)

Also for Y we observe varying trends for the different states even for pp collisions! (More info on next slide)

### In small systems we observe enhancement with event activity

In this case we observe different trends with event activity Caveat: should study binary scaling (but this does not work for pp)

54

## Summary of quarkonia results

- The qualitative results are in agreement with what one expects for a Quark Gluon Plasma
- The advantage of LHC is that all quarkonia states have been measured making the measurements less sensitive to assumptions about feed-down corrections
- The quantitative picture is complicated and there are many issues that are even interesting for pp phenomenology

#### HARD PROBES: JETS

56

## Jets as probes of the QGP

- The idea to use jets to probe the QGP goes back to Bjorken. He made a first study of collisional energy loss but never published this as he realized that radiative energy loss was much more important
- The phenomenology is quite difficult and has many variants so I focus on the experimental results

## Jet quenching in the QGP

For color charges one expects energy losses of GeV/fm vs MeV/cm for electric charges in normal atomic matter. 10,000,000,000,000,000 (10<sup>16</sup>) times larger energy loss.

## High p<sub>T</sub> particles: a proxy for jets

At RHIC very few studies have been done with jets. Instead high  $p_T$  particles have been used to study jet quenching.

At LHC high p<sub>T</sub> results are also used but additionally there are many jet studies.

Results at LHC are qualitatively similar to results from RHIC with a large suppression in central collisions New things were the clear rise with  $p_T$ LHC has huge advantage due to the larger jet Xsection.

hadrons from jet fragmentation

### Jets in pp

hadrons from quenched jet

## CONTRACTOR OF CO

## Jets in Pb-Pb (ATLAS)

Jet asymmetry – away side jet is absorbed/modified by the medium
 Advantage of jets is that they "map" onto the QCD degrees of freedoms:
 quarks and gluons (more complicated in heavy ion collisions)
 Advantage of ATLAS and CMS is larger acceptance

#### Jets in Pb-Pb (CMS)

Christiansen, Lund

<u>e</u>.

QGP

Heavy-ion physics and the

### Quantifying the dijet asymmetry

$$A_{\rm J} = \frac{E_{\rm T1} - E_{\rm T2}}{E_{\rm T1} + E_{\rm T2}}$$

Where  $E_{T1}(E_{T2})$  is the transverse energy of the leading (subleading) jet ( $E_{T1}$ >100 GeV and  $E_{T2}$ >25 GeV).

Notice that the jets are still back-to-back!

## Looking into the jet structure

The motivation for these studies was:

- to recover some of the radiated energy (in principle jets did not have to suppressed!)
- to study how the FF is modified

### Two examples of ideas for modified FFs

## Selecting dijet events and comparing to pp

The A<sub>1</sub> selection introduces the same bias on the dijet samples

#### **FYST17** 68

# Surprisingly the jet structure is the same! (tracks with $p_T > 4 GeV/c$ )

The result shows that quenched jets looks like pp (vacuum) jets! Even in the case where A<sub>J</sub> is large and for the subleading jet!

One proposed solution is that the medium cannot resolve the jet constituents (Phys.Lett. B725 (2013) 357-360). So for the medium the jet will look essentially as a single parton

and so all fragments are quenched coherently!

# The finer structure of the fragmentation function

Phys. Rev. C 90, 024908

This analysis considers tracks down to  $p_T = 1 \text{ GeV/c}$ The modifications are sitting at low  $p_T$ , mainly  $p_T < 3 \text{GeV/c}$ 

## Tracking the energy loss

CMS have shown that the energy loss can be recovered at low  $p_T$  at large  $\Delta\eta$  and large  $\Delta\varphi$ 

## Charged π, K, and p spectra in pp and Pb-Pb collisions

ALICE , PLB 736, 196 (2014)

### The nuclear modification factor

For  $p_T < 8 \text{ GeV}/c$ :  $R_{AA}$  for  $\pi$  and K compatible and smaller than  $R_{AA}$  for p. At high  $p_T$  above 10 GeV/c the  $R_{AA}$  for  $\pi$ , K and p are compatible.

## R<sub>AA</sub> double ratios

To obtain the best estimate for the similarity between the  $R_{AA}$  of  $\pi$ , K, and p we computed the double ratio of  $R_{AA}$ . This cancels the most of the common systematic uncertainties.

Similarity between  $R_{AA}$  at high  $p_T$ :  $\pi/K$ :  $\approx 10\%$  (1 $\sigma$ )  $\pi/p$ :  $\approx 20\%$  (1 $\sigma$ )

The improvement in systematic precision is almost an order of magnitude, compared to lower energy STAR results.

## Conclusions on jets

- High p<sub>T</sub> particles (and jets) were one of the hottest topics at RHIC where they were difficult to measure
  - And it seemed at RHIC that jets were modified in a spectacular way giving rise to exotic effects
- At LHC the picture we have of jet quenching has turned out to be surprisingly simple
  - Experimentally the jets seem to first loose energy in the QGP and then afterwards to fragment as vacuum jets

The energy loss is observed as soft particles at large angles

### **SOFT MEDIUM PROPERTIES**

Because of the similarity with Stefan-Boltzmann energy density for a quark-gluon gas: QGP should be weakly coupled At a deeper level this is also what we expect from asymptotic freedom

### **Radial flow**

- Flow in general plays a very important role in heavy-ion collisions.
- We believe that flow in the partonic phase is imprinted on the final state hadrons at freeze out.

Flow velocity  $\beta_r \rightarrow mass$  dependent boost:

 $p_T \sim \gamma \beta_r m$  (for particle initially at rest)

## Radial flow

(P. Christiansen, Lund QGP Heavy-ion physics and the

Aligned

- Flow in general plays a very important role in heavy-ion collisions.
- We believe that flow in the partonic phase is imprinted on the final state hadrons at freeze out.

Flow velocity  $\beta_r \rightarrow mass$  dependent boost:

 $p_T \sim \gamma \beta_r m$  (for particle initially at rest)

## Evolution of the heavy-ion collision

Mainly this period where flow build up

# Elliptic flow requires early strong interactions to form

Zhang, Gyulassy, Ko, Phys. Lett. B455 (1999) 45

 Each nucleon-nucleon interaction produces on average a spherical symmetric distribution.
Only by interacting elliptic flow is generated

### Mass ordering of the elliptic flow

The mass ordering is characteristic of flow since heavier particles are pushed out to higher  $p_{\rm T}$ 

Surprisingly this is well described by nearly ideal hydrodynamics

# Some simulation movies of hydrodynamics

<u>https://www.youtube.com/watch?v=G18pyV</u>
<u>OmSRw</u>

## Ridge (ATLAS)

One can study flow using two particle correlations. Here  $2 < p_{T1}, p_{T2} < 3$  GeV/c

The long range correlations are imprinted by the flow because **the initial elliptic overlap is a global property of a collision!** 

For completeness:

Singles:  $\frac{dN}{df}$   $\mu$  1 +  $\mathring{a}$  2v<sub>n</sub> cos n (f -  $\Upsilon_n$ ) EP method  $\frac{dN}{dDf} \propto 1 + \sum_{n} 2v_{n}^{a}v_{n}^{b}\cos(nDf)$  **2PC method** Pairs:

### Flow fluctuations

Because the nuclei are not homogenous the initial state can be quite asymmetric giving rise to e.g. triangular flow! Famous paper: B. Alver, G. Roland, Phys.Rev. C81 (2010) 054905 (420 citations)

# OUT THE REAL PROPERTY OF THE P

# Elliptic flow and triangular flow is almost ideal!

88

FYST17

- Huge flow at intermediate p<sub>T</sub>:
  - 2 times more particles in plane than out Nearly ideal fluid
- Significant higher order flow caused by fluctuations also described by nearly ideal hydro + initial state

The shear force is given as  $F=\eta Av/d$ The shear vicosity-to-entropy density ratio,  $\eta/s$ , is a unitless quantity for characterizing fluids. For the QGP,  $\eta$ /s is extremely small!

# The QGP is less like a crowd and more like a synchro team

90

Big theoretical challenges:

Why is the QGP behaving like a liquid? (next slide) how to go from initial random collisions to organized state in a VERY short time (<1fm/c~10<sup>-23</sup>s). This remains to be understood

## How to understand this? AdS-CFT

- How to reconcile nearly ideal fluid with energy density like a relativistic gas?
- AdS-CFT correspondence (conjecture)
  - J.M. Maldacena, Adv.Theor.Math.Phys.2:231-252, 1998, ~10,000 citations on inspire=most cited
  - Duality between <u>weakly</u> coupled gravity like theory (AdS) and <u>strongly</u> coupled QCD like theory (CFT)
  - QCD like theory, but conformal (no confinement, no running coupling) (like QGP!) infinite Ncolors SUSY

## AdS-CFT

Two very important results:

Conjectured bound on shear viscosity:  $\eta/s \ge 1/(4\pi) \sim 0.08$ 

 Viscosity in strongly interacting quantum field theories from black hole physics, P. Kovtun, D.T. Son, A.O. Starinets, Phys.Rev.Lett. 94 (2005) 111601. (~1400 citations on inspire.)

Possibility of infinitely strong coupling at energy density of <sup>3</sup>/<sub>4</sub> SB gas

## The QGP fluid compared to other fluids

## The QGP fluid compared to other fluids

#### Strongly interacting ultra-cold Li atoms released from a trap

http://www.physics.ncsu.edu/jet/index.html

η/s ~ 7 x 1/4π

## Conclusions about soft physics

- The medium produced in heavy-ion collisions behaves like a nearly perfect liquid. In fact like the most perfect liquid we know!
- This was completely unexpected based on lattice QCD results
- We can get some insight into the liquid nature from AdS-CFT but so far this does not give a full picture e.g. it does not yet describe jet quenching

### **COLLECTIVITY IN SMALL SYSTEMS**

## The effect of system size: Macroscopic effects in small systems?

Hot nuclear matter

Cold nuclear matter

### The rise of the double ridge

 Double ridge structure reminiscent of azimuthal flow in Pb-Pb collisions

## Ridges in all systems

The perfect liquid is produced in all systems suggesting that small QCD systems produce "macroscopic" matter

# Using Particle IDentification to study the double ridge

Clear mass ordering suggests flow

# Particle ratios in p-Pb and Pb-Pb show similar features

102

- Characteristic evolution of  $p/\pi$  and  $\Lambda/K_s^0$  with multiplicity is reminiscent of Pb-Pb where it is believed to be due to radial flow
- NB! The solid boxes for p-Pb ratios indicate the uncorrelated systematic error ⇒ the relative trend can be measured rather precisely

## Which models can capture these

### features?

#### Models

- Blast-wave (next slides)
- EPOS LHC (full event generator including hydro)
- Krakow (hydro calculation focused on low  $p_{T}$ )
- DPMJet (PHOJET pp + nuclei via Glauber-Gribov theory)
- Only models which employ hydrodynamics can describe the p<sub>T</sub> spectra

## A blast wave study of the data

Schnedermann et al, Phys. Rev. C 48, 2462 (1993)

- Simultaneous fits  $\pi: 0.5 < p_T < 1.0 \text{ GeV/c}$   $K: 0.2 < p_T < 1.5 \text{ GeV/c}$   $pp: 0.3 < p_T < 1.5 \text{ GeV/c}$   $p: 0.3 < p_T < 3.0 \text{ GeV/c}$  $pp: 0.5 < p_T < 2.5 \text{ GeV/c}$
- Adding  $K_{S}^{0}(0.0 < p_{T} < 1.5 \text{ GeV/c})$ and  $\Lambda (0.6 < p_{T} < 2.0 \text{ GeV/c})$ does not significantly change extracted parameters

## A blast wave study of the data

The description of p-Pb and pp data by the blast-wave fit is reasonable without being excellent

### A blast wave study of the data

The  $p_T$  region where the blast-wave fit describes the data is in general broader for Pb-Pb

## Summarizing the results from the blast-wave studies

## There is a strong common trend between the parameters extracted from Pb-Pb and p-Pb

## Summarizing the results from the blast-wave studies

Even the pp data seems to follow the same trend! It seems that if we ascribe the change in spectral shape to radial flow in p-Pb then the same can be done in pp

### Summarizing the results from the blast-wave studies

BUT also simulated PYTHIA8 pp events follow a <u>qualitatively</u> similar trend when Color Reconnection (CR) is enabled CR has been shown to mimic radial flow but without requiring the formation of a medium

#### The "flow peak" in pp

Realized that Color Reconnection in PYTHIA gives rise to flow like boosts, A. O. Velasquez, P. Christiansen, et al, PRL 111, 042001 (2013). For details, see T. Sjöstrand, arXiv:1310.8073.

Can be interpreted different ways: CR as microscopic model of flow or one needs (hydro) flow in pp.

#### 111 FYST17

Need bulk physics (medium) to describe increase!

QGP

Heavy-ion physics and the

Project: **"Pinning down the origin of collective effects in** small collision systems"

Grant: SEK 26 200 000 over five years Principal investigator: **Associate Professor Peter Christiansen, Lund University** 

### P. Christiansen (Partikelfysik) L. Lönnblad (Teoretisk Högenergifysik)

### Conclusions

- The reason we believe in a QGP
  - We clearly form a medium that behaves as a nearly ideal fluid with a temperature in the range given by LQCD
  - It dissolves quarkonia as expected indicating that there are strong screening effects = high density of colored objects
  - It quenches jets and gives rise to energy losses of order GeV/fm which is as expected from color fields
- The challenge to this paradigm is that we now observe medium like effects in small systems
  - We need to understand this better!

### What I did not cover

- Charged multiplicity and hadronization
  - Color Glass Condensate and Statistical Model
- Quark scaling of elliptic flow
  - Recombination of quark like degrees of freedom (picture is more complicated at LHC)
- Quenching and flow of heavy quarks
  - Suggests that there are also large collisional energy loss

### Why are the small systems so critical to understand

- Before we were happy to have
  - Small systems = QCD
    - Phenomenology: PYTHIA
  - Large systems = QGP
    - Phenomenology: Glauber + hydro + stat. model + some hadronic rescattering

# Geometry: is the Pb-Pb centrality evolution described by hydro?

118

 Near ideal hydrodynamics with some implementation of the hadronic phase describes well p<sub>T</sub> spectra in central collisions

#### Geometry: is the Pb-Pb centrality evolution described by hydro? Pb-Pb 0-5% Pb-Pb 70-80%

p<sub>1</sub> (GeV/c)

119

Phys. Rev. Lett. 109, 252301 (2012)

The same models fail to describe the  $p_{T}$  spectra in peripheral collisions

Typically hydro has not been expected to work in peripheral collisions but if it is at work in p-Pb and pp collisions should it not work there?

### Why is this a problem

- Our description of the medium is not only critical for the low p<sub>T</sub> observables, the jet quenching also relies on our medium properties
- If we cannot resolve this issue then we are a bit stuck
- Need to understand if a medium is also created in small systems!
  - My own view: need to look for energy loss in small systems

#### Backup slides

### Motivation: searching for "footprints" of the energy loss

Gluons lose 2 times (color factor) more energy than quarks in the medium

Several other ideas:

Color flow (Sapeta, Wiedemann, EPJC55, 293, 2008)

Color structure (Aurenche, Zakharov, EPJC71, 1829, 2011) In medium formation time effects

(Bellwied, Markert, PLB691, 208, 2010)

Magnitude of the effects are large (50+%) since it is linked to the large energy loss

### Why expect particle species

dependent  $R_{AA}$  at high  $p_T$ ?

- Large effects at intermediate p<sub>T</sub> does this effect just disappear?
- . The low value of  $\mathsf{R}_{\mathsf{A}\mathsf{A}}$  suggests that most hard partons interacts strongly with the medium

S. Sapeta and U.A. Wiedemann, Eur.Phys.J. C55 (2008) 293:

- Indirect
  - "in all models of radiative parton energy loss, the interaction of a parent parton with the QCD medium transfers color between partonic projectile and target. <u>This changes the color flow in the parton</u> <u>shower and is thus likely to affect hadronization</u>."
  - Direct
    - "In addition, flavor or baryon number could be exchanged between medium and projectile."

## A general model with particle species dependent modifications

- Effect inside jet
- But for  $p_T >> 8$  GeV/*c* we expect all hadrons to belong to jets
